SEMIVOLATILE ORGANICS ANALYSIS DATA SHEET FIELD ID.

TENTATIVELY IDENTIFIED COMPOUNDS

B-119

Lab Name: FMETL NJDEP: 13461

Project: 980211 Case No.: 4189 Location: M14 SDG No.:

Matrix: (soil/water) SOIL Lab Sample ID: 4189.14

Sample wt/vol: 10.06 (g/ml) G Lab File ID: BNA02004.D

Level: (low/med) LOW Date Received: 01/13/99

% Moisture: 8.8 decanted: (Y/N) N Date Extracted: 01/20/99

Concentrated Extract Volume: 1000 (uL) Date Analyzed: 01/22/99

Injection Volume: 1.0 (uL) Dilution Factor: 1.0

GPC Cleanup: (Y/N) N pH: 7

CONCENTRATION UNITS:

Number TICs found: 4 (ug/L or ug/Kg) UG/KG

CAS NUMBER	COMPOUND NAME	RT	EST. CONC.	Q
1.	unknown	12.46	880	J
2. 074367-34-3	Propanoic acid, 2-methyl-, 3-hydr	12.75	1100	JN
3.	unknown	18.42	1600	J
4. 074685-33-9	3-Eicosene, (E)-	23.87	2500	JN

EXECUTIVE SUMMARY

VERSAR, Inc. (VERSAR) has been contracted by the United States (U.S.) Army Installation, Fort Monmouth (Fort Monmouth), Directorate of Public Works (DPW), Fort Monmouth, New Jersey, to prepare a Remedial Investigation Report (RIR) for data collected during recent sediment sampling events at the M-12/M-14 Landfill Sites (Site). This report describes the remedial investigation activities conducted at the Site on April 10, 2000.

The Site is located on the Main Post Area of Fort Monmouth on the north and south side of Husky Brook, west of Murphy Drive, and occupies approximately 9.0 acres. The Site is comprised of both the M-12 and the M-14 landfills. The M-12 landfill consists of two separate areas, a northeast area and a southwest area. According to the Roy F. Weston (WESTON) report, *Site Investigation, Fort Monmouth, New Jersey, Main Post and Charles Wood Areas, Site Investigation Report (December 1995)*, both landfills were historically used for the disposal of domestic and industrial wastes. In the 1995 Site Investigation (SI), WESTON conducted a geophysical survey, groundwater sampling and tidal monitoring at each landfill. In addition, surface water samples were obtained from the portion of Husky Brook that is adjacent to the M-14 landfill. WESTON recommended that a long-term groundwater monitoring program be developed and implemented at the M-12 and M-14, but provided no recommendations related to Site-specific sediment quality. A long-term surface water monitoring program was also recommended for M-14.

Other studies conducted at similar Main Post Landfill sites (M-2 and M-8) found polychlorinated biphenyl (PCB) -containing materials (e.g., electrical ballasts) disposed of in each landfill. In addition, PCBs were detected in soil and/or groundwater at both the M-2 and M-8 Landfill sites. Therefore, assuming that other landfills on the Main Post had received similar waste materials, the DPW initiated a sediment sampling investigation in the second quarter of 2000 to evaluate potential impacts to stream sediments in creeks and/or brooks running adjacent to the Main Post and Charles Wood (CW-3A only) landfill sites. The M-12/M-14 Landfill Site was included in the sediment sampling program to supplement the WESTON findings related to soil, surface water and groundwater matrices.

To determine potential PCB-related impacts to sediments in Husky Brook, the DPW obtained 25 sediment samples on April 10, 2000, including two duplicate samples for quality assurance/quality control (QA/QC), from the surface and near-surface sediments of Husky Brook. The samples were obtained along the 1,700-foot portion of Husky Brook that flows through the M-12/M-14 Site. All 25 sediment samples were analyzed for PCBs and compared to the sediment sampling guidance concentrations defined in the New Jersey Department of Environmental Protection (NJDEP) *Guidance for Sediment Quality Evaluations (November 1998).* The analytical data is summarized in table form in this RIR. VERSAR developed this RIR based on the evaluation of these sediment data.

Data presented in Section 3.0 of this RIR indicate that there was one anomalous detection of PCBs in a duplicate sample but that no PCBs were detected in any of the 25 samples obtained from Husky Brook. Based on NJDEP guidance criteria, the results indicate that there are no PCB-related impacts to sediments in Husky Brook, which flows through the M-12/M-14 Landfill Site.

Based on the results of this sediment quality evaluation, no PCBs were detected above the NJDEP guidance criteria for sediment quality in any sample, and no potential exists for long-term adverse benthic effects in Husky Brook associated with the M-12/M-14 Landfill Site. Therefore, No Further Action is recommended for the M-12/M-14 Landfill Site related to potential PCB impacts to the sediments of Husky Brook.

1.0 INTRODUCTION

VERSAR has been contracted by the U.S. Army Installation, Fort Monmouth, DPW, Fort Monmouth, New Jersey to prepare an RIR and sediment quality evaluation for the Site located at the Fort Monmouth Main Post Area. This report addresses the remedial investigation activities performed at the Site on April 10, 2000.

1.1 Objectives

Other studies conducted at similar Main Post Landfill sites (M-2 and M-8) found PCB-containing materials (e.g., electrical ballasts) disposed of in each landfill. In addition, PCBs were detected in soil and/or groundwater at both the M-2 and M-8 Landfill sites. Therefore, assuming that other landfills on the Main Post had received similar waste materials, the DPW initiated a sediment sampling investigation in the second quarter of 2000 to evaluate potential impacts to stream sediments in creeks and/or brooks running adjacent to the Main Post and Charles Wood (CW-3A only) landfill sites. The M-12/M-14 Landfill Site was included in the sediment sampling program to supplement the earlier WESTON findings related to the soil, surface water and groundwater matrices.

The objective of this RIR is to determine potential PCB-related impacts to stream sediments in Husky Brook, which flows through the M-12/M-14 Landfill Site. The remedial investigation was conducted in accordance with New Jersey Administrative Code (NJAC) 7:26E - *Technical Requirements for Site Remediation* (February 2003) and NJDEP *Guidance for Sediment Quality Evaluations* (November 1998).

The remedial investigation encompassed the following:

- Obtaining surface and near-surface sediment samples approximately every 100 feet along the bottom of Husky Brook, which flows through the M-12/M-14 Landfill Site.
- Analyzing the samples for PCBs by United States Environmental Protection Agency (USEPA) Method 8082.
- Comparing the analytical results to the screening level criteria defined in the NJDEP *Guidance for Sediment Quality Evaluations* (November 1998).

1.2 Report Organization

This report is organized to minimize repetition. **Section 2.0** provides background information and a general description of the M-12/M-14 Landfill Site located at the Fort Monmouth Main Post area. **Section 3.0** describes and summarizes the sampling procedure and activities. **Section 4.0** presents analytical results and compares those results with NJDEP guidance criteria. **Section 5.0** provides a summary of the findings of the remedial investigation, and requests a No Further Action determination from the NJDEP.

2.0 SITE BACKGROUND AND ENVIRONMENTAL SETTING

The following sections describe the Site background and environmental setting of the area surrounding Fort Monmouth and the M-12/M-14 Landfill Site. Included is a description of the Site location, background, current conditions and environmental setting.

2.1 Site Location and Description

Fort Monmouth is located in the central-eastern portion of New Jersey in Monmouth County, approximately 45 miles south of New York City and 70 miles northeast of Philadelphia (**Figure 2-1**). In addition to the Main Post, the installation includes two subposts, the Charles Wood Area and the Evans Area. The Main Post encompasses approximately 630 acres and is generally bounded by State Highway 35, Parkers Creek, Lafetra Creek, the New Jersey Transit Railroad and a residential area to the south. The post was established in 1918 during World War I (WWI) as an Army Signal Corps training center. The Main Post currently provides administrative, training, and housing support functions, as well as providing many of the community facilities for Fort Monmouth. The primary mission of Fort Monmouth is to provide command, administrative, and logistical support for Headquarters, U.S. Army Communications and Electronics Command (CECOM). CECOM is a major subordinate command of the U.S. Army Materiel Command (AMC) and is the host tenant at Fort Monmouth.

The M-12/M-14 Landfill Site is located on the north and south sides of Husky Brook, west of Murphy Drive, in the Main Post Area (**Figure 2-2**). The approximate area of the M-12/M-14 Landfill Site is 389,300 feet^2 (9.0 acres). The M-12 landfill consists of two areas, a northeast area and a southwest area. Husky Brook flows along the northern boundary of the M-14 landfill and eventually between both the M-12 and M-14 landfills, for a distance of approximately 1,700 feet. It ultimately flows into Oceanport Creek. The bank of Husky Brook contains trees, bramble and small vegetation upstream and large rocks downstream. Portions of Husky Brook have been repaired/restored as part of a streambank Landfill project.

The various Landfill Sites on the Main Post are identified on **Figure 2-3**. The map is provided to identify:

- the relative location of each of the former landfill sites due to the similarity of past site uses, the types debris deposited at these locations, and the nature of the contaminants identified in soil, groundwater and/or sediment samples during the present and former investigations; and
- the proximity and interrelatedness of the adjacent surface water bodies.

2.2 Site Background

The WESTON report, *Site Investigation, Fort Monmouth, New Jersey, Main Post and Charles Wood Areas, Site Investigation Report* (December 1995), summarized surface

water sampling events that have been conducted since February 1986 for samples collected in Husky Brook. These sampling events were part of a former New Jersey Pollutant Discharge Elimination System (NJPDES) Permit and were obtained in that portion of Husky Brook that flows along the northern border of the M-14 landfill. From these sampling events, a report prepared by WESTON in 1993 (*Investigation of Suspected Waste Sites at Fort Monmouth, New Jersey*) indicates that no compounds were detected above NJDEP surface-water criteria.

The WESTON SI Report (WESTON, 1995) summarizes the results of a geophysical survey for determining landfill boundaries, groundwater sampling and tidal monitoring. In addition, surface-water samples were obtained in that portion of Husky Brook flowing along the northern boundary of the M-14 landfill. The surface water samples were sampled for volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides, PCBs and TAL metals. According to the WESTON SI report, VOCs, SVOCs, pesticides and PCBs were not detected above laboratory method detection limits (MDLs) in the samples. For the TAL metals analysis, no metals were detected at concentrations above NJDEP surface water criteria. The WESTON SI report recommended the implementation of a long-term groundwater monitoring program due to the historical Site use as a landfill. The present investigation was undertaken to further expand the WESTON SI report and assess the potential PCB-related impacts to stream sediments based on past Site use.

2.3 Current Conditions

VERSAR conducted a site walk on December 11, 2000 to assess current conditions at the M-12/M-14 Landfill Site. The M-12 site consists of two areas separated by a tributary to Husky Brook, which is bounded by trees and shrubs. The western M-12 area was recently backfilled and graded with black fill material. There was no vegetation present at the time of the Site walk, with the exception of areas along Husky Brook on the north side of the site, which was bounded with trees. The eastern portion of the M-12 site was an open field of grass.

M-14, located on the north side of Husky Brook, consists of an open field with some trees. This area was landscaped, with the grass cut and the trees pruned. On the eastern side of the Site is a playground. Site photographs are provided in **Appendix A**.

2.4 Environmental Setting

The following is a description of the geological/hydrogeological setting of the area surrounding the M-12/M-14 Landfill Site. Included is a description of the regional geology and hydrogeology of the area surrounding Fort Monmouth, as well as descriptions of the local geology and hydrogeology of the M-12/M-14 area.

2.4.1 Regional Geology

Monmouth County lies within the New Jersey Section of the Atlantic Coastal Plain physiographic province. The M-12/M-14 Landfill Site is located in what may be referred to as the Outer Coastal Plain subprovince, or the Outer Lowlands. The geologic map of New Jersey is provided as **Figure 2-4**.

In general, New Jersey Coastal Plain formations consist of a seaward-dipping wedge of unconsolidated deposits of clay, silt, sand and gravel. These formations typically strike northeast-southwest with a dip ranging from 10 to 60 feet per mile and were deposited on Precambrian and lower Paleozoic rocks (Zapecza, 1989). These sediments, predominantly derived from deltaic, shallow marine, and continental shelf environments, date from Cretaceous through the Quaternary Periods. The mineralogy ranges from quartz to glauconite.

The formations record several major transgressive/regressive cycles and contain units, which are generally thicker to the southeast and reflect a deeper water environment. More than 20 regional geologic units are present within the sediments of the Coastal Plain. Regressive, upward coarsening deposits are usually aquifers (e.g., Englishtown and Kirkwood Formations, and the Cohansey Sand), while the transgressive deposits act as confining units (e.g., the Merchantville, Marshalltown and Navesink Formations). The individual thickness for these units varies greatly (e.g., from several feet to several hundred feet). The Coastal Plain deposits thicken to the southeast from the Fall Line (e.g., a boundary zone between older, resistant rocks and younger, softer plain sediments) to greater than 6,500 feet in Cape May County (Brown and Zapecza, 1990).

Based on the regional geologic map (Jablonski, 1968), the Cretaceous age Red Bank and Tinton Sands outcrop at the Main Post Area. The Red Bank Sand conformably overlies the Navesink Formation and dips to the southeast at 35 feet per mile. The upper member (Shrewsbury) of the Red Bank Sand is a yellowish-gray to reddish brown clayey, medium-to-coarse-grained sand that contains abundant rock fragments, minor mica and glauconite (Jablonski). The lower member (Sandy Hook) is a dark gray to black, medium-to-fine grained sand with abundant clay, mica and glauconite.

The Tinton Sand conformably overlies the Red Bank Sand and ranges from a clayey medium to very coarse-grained feldspathic-quartz and glauconite-sand to a glauconitic-coarse sand. The color varies from dark yellowish orange or light brown to moderate brown and from light olive to grayish olive. Glauconite may constitute 60 to 80 percent of the sand fraction in the upper part of the unit (Minard, 1969). The upper part of the Tinton is often highly oxidized and iron oxide encrusted (Minard, 1969).

The Kirkwood Formation (part of the Kirkwood-Cohansey system) crops out southeast of the Main Post and dips to the southeast at a slope of 20 feet per mile (Jablonski, 1968). The Kirkwood Formation consists of alternating layers of sand and clay. The upper unit is a light gray to yellowish-brown, fine-grained quartz sand with quartz nodules and small pebbles. The lower unit is a brown silt in Monmouth County (Jablonski, 1968).

2.4.2 Regional Hydrogeology

Fort Monmouth lies in the Atlantic and Eastern Gulf Coastal Plain groundwater region (Meisler et al., 1988). This groundwater region is underlain by undeformed, unconsolidated to semi-consolidated sedimentary deposits. The chemistry of the water near the surface is variable with low dissolved solids and high iron concentrations. The water chemistry in areas underlain by glauconitic sediments (such as Red Bank and Tinton Sands) is dominated by aluminum, calcium, magnesium, manganese and iron. The sediments in the area of Fort Monmouth were deposited in fluvia-deltaic to nearshore environments.

The water table aquifer in the Main Post area is identified as part of the "composite confining units," or minor aquifers. The minor aquifers include the Navesink formation, Red Bank Sand, Tinton Sand, Hornerstown Sand, Vincentown Formation, Manasquan Formation, Shark River Formation, Piney Point Formation and the basal clay of the Kirkwood Formation.

Well records indicate that wells installed in the Red Bank and Tinton Sands produce 2 to 25 gallons per minute (gpm). Water in these upper hydrogeologic units is typically encountered at shallow depths below ground surface (2 to 9 feet bgs). However, domestic wells are generally screened deeper in these upper hydrogeologic units. The shallow water table conditions in the Tinton and Red Bank Sands, and the similar composition of these sands within the Kirkwood Formation, suggest that the Tinton-Red Bank-Kirkwood sequence forms a single, laterally continuous aquifer. Water in this water-table aquifer flows east toward the Atlantic Ocean. Local topography tends to deflect the flow toward local depressions.

As stated in the SI Report (WESTON, 1995), NJAC 7:9-6, *Groundwater Quality Standards* (GWQS) establishes groundwater quality criteria for different classes of groundwater. Class II-A, which is defined as all groundwater that is not classified as one of the other special classes, is the appropriate class for groundwater at Fort Monmouth. The primary designated use for Class II-A groundwater is potable water; secondary uses include agricultural and industrial water.

Shallow groundwater is locally influenced within the Main Post Area by the following factors:

- Tidal influence (based on proximity to the Atlantic Ocean, rivers and tributaries)
- Topography
- Nature of the fill material within the Main Post Area
- Presence of clay and silt lenses in the natural overburden deposits
- Local groundwater recharge areas (e.g., streams, lakes)

Due to the fluvial nature of the overburden deposits (e.g., sand and clay lenses), shallow groundwater flow direction is best determined on a case-by-case basis. The groundwater

flow in the vicinity of the M-12/M-14 Landfill Site is assumed to be to the north for the M-12 landfill, in the direction of Husky Brook, and south for the M-14 landfill, also towards Husky Brook.

2.4.3 Local Geology/Hydrogeology

As presented in the WESTON SI, the field logs from monitoring well installations indicate that the lithology at M-12/M-14 consists of a thin soil cover (0.3 feet) underlain by fill material. The components of the fill materials observed in the borings consisted of organic debris and coal fragments intermixed with a moderate to poorly sorted olive-green-brown silty medium-fine-grained sand with little clay. Groundwater saturation was observed at approximately 2 feet bgs across the site. Water-level elevation data collected during the WESTON SI indicate that local groundwater flow is west toward Husky Brook.

2.4.4 Soils

According to the U.S. Department of Agriculture (USDA), Soil Conservation Service, Monmouth County Soil Survey, the majority of the Main Post area is covered by urban land (**Figure 2-5**). The soil survey described urban land as areas where concrete, asphalt, buildings, shopping centers, airports or other impervious surfaces cover 80 percent or more of the surface. In addition, the survey indicated that the natural subsurface soils have largely been replaced with artificial or foreign fill materials (developed land with disturbed soils). The following soil series and classification units are mapped in the Main Post Area:

- DoB Downer sandy loam (with 2 to 5 percent slopes);
- FrB Freehold sandy loam (with 2 to 5 percent slopes);
- FUB Freehold sandy loam/urban land complex (with 0 to 10 percent slopes);
- HV Humaquepts, frequently flooded;
- KvA Kresson loam (with 0 to 5 percent slopes);
- UA Udorthents, smoothed; and
- UD Udorthents – urban land complex (with 0 to 3 percent slopes).

The Downer series soils are well-drained soils that are found on uplands and terraces. The soils are formed in acid, silty coastal plain sediments. The Freehold soils are also well drained and are formed in acid, loamy, coastal plain sediments that, by volume, are 1 to 10 percent glauconite and are found on uplands. The Humaquepts soils are somewhat poorly- to very poorly- drained soils that are formed in stratified, sandy, or loamy sediments of fluvial origins. The Humaquepts soils are located on the floodplain and are subject to flooding several times each year. The Kresson loam is a nearly level to gently sloping soil and is somewhat poorly drained. The soil is found on low divides and in depressions. The Udorthents soils have been altered by excavation or filling activities. In filled areas, these soils consist of loamy material that is more than 20 inches thick. The filled areas include floodplain, tidal marshes and areas with moderately, well drained to very poorly drained soils. Some Udorthent soils contain concrete, asphalt, metal and

glass. The soils in the vicinity of the M-12/M-14 Landfill Site are classified as UA to UD, Udorthents, smoothed to Udorthents, urban land complex.

2.4.5 Topography and Surface Drainage

Over the last 80 years, the natural topography of Fort Monmouth has been altered by excavation and filling activities by the military. The M-12/M-14 Landfill Site is located on the floodplain of Husky Brook. The USGS topographic map (**Figure 2-1**) shows that the land surface of the Site is relatively flat at an elevation of less than 20 feet above mean sea level (amsl).

Surface water bodies from the western part of the Main Post flows into the Lafetra Creek to the north or into the Mill Creek to the south. The USGS topographic map (**Figure 2-1**) shows the Lafetra Creek as Parkers Creek Branch and Mill Creek as Wampum. Both Mill and Lafetra Creek originate off-post. Mill Creek flows along the southern boundary of the Main Post, turning north just past the Auto Craft Shop. Mill Creek is channelized and flows past the north side of the M-2 Landfill. Lafetra Creek forms the northern boundary of the Main Post and joins Mill Creek to form Parkers Creek. Parkers Creek flows eastward along the northern boundary and joins Oceanport Creek east of the post. Most of Parkers Creek, Lafetra Creek and Mill Creek are tidally influenced.

The U.S Fish and Wildlife Service (FWS) National Wetland Inventory Long Branch quadrangle maps indicate the presence of wetlands at the Main Post. Parkers and Oceanport Creeks are classified as estuarine intertidal aquatic beds. The area of Parkers Creek and the part of Oceanport Creek/Husky Brook are classified as estuarine intertidal emergent wetlands. Lafetra Creek and Mill Creek are classified as riverine lower perennial open water/unknown bottom.

3.0 SEDIMENT SAMPLING ACTIVITIES

Fort Monmouth DPW conducted sediment sampling in Husky Brook to evaluate potential PCB-related impacts to stream sediments associated with the M-12/M-14 Landfill Site. On April 10, 2000, 11 borings were installed approximately every 100 feet along the bottom of Husky Brook, as shown in **Figure 3-1: M-12/M-14 Boring Location Map.** The locations extended from downstream at Boring B-1 near Murphy Drive to upstream at Boring B-11, and were sampled accordingly in that order (see chain-of-custody records, **Appendix D**). The sediment sampling was conducted in accordance with the *Installation Restoration Program Sediment Sampling Plan for Nine Former Landfill Sites* (TVS, March 2000) presented in **Appendix B**. The Sediment Sampling Plan (SSP) was approved by the NJDEP on April 3, 2000.

Twenty-five sediment samples were collected, including two duplicate samples for QA/QC, from 11 borings using a Wildco Sediment Sampler. The samples were obtained along the 1,700-foot portion of Husky Brook that flows through the Site. Sample depths ranged from surface (0 to 6 inches) to near-surface (6 inches to 12 inches below grade) at each boring location, with the exception of Borings B-1, B-4 and B-6, which were also sampled at a depth of 18 inches to 24 inches below grade. The samples consisted of black to brown fine sandy silt to green/black clay and sandy clay with black bands, some organic material and small angulars. Boring logs are provided in **Appendix C**.

Sampling equipment was thoroughly decontaminated before and after each use, in accordance with the SSP. The sediment samples were collected using a Wildco Sampler and immediately placed in laboratory-supplied bottleware. The sample containers were labeled, sealed, packed in ice and transported to the Fort Monmouth Environmental Testing Laboratory (FMETL), New Jersey Certification Number NJDEP 13461, under proper chain-of-custody procedures. The samples were analyzed by FMETL on April 10, 2000 for PCBs utilizing USEPA Method 8082. Copies of the chain-of-custody for the laboratory analysis can be found in **Appendix D**. A summary of the borings, including sample IDs, sample collection date/time, sample depths, northing/easting coordinates, analysis and general soil descriptions is provided in **Table 3-1: Sediment Sample Summary**.

4.0 SITE CHEMICAL CHARACTERIZATION

On April 10, 2000, DPW collected 25 sediment samples along the bottom of Husky Brook to evaluate potential PCB-related impacts to stream sediments from the adjacent M-12/M-14 Landfill Site. Eleven borings were installed at the approximate rate of one per 100 feet along the bottom of the brook. Twenty-five samples were collected from 11 borings at depths ranging from surface (0 to 6 inches) to near-surface (6 inches to 12 inches below grade) at each boring location with the exception of Borings B-1, B-4 and B-6, which were also sampled at a depth of 18 inches to 24 inches below grade. Samples were identified in the field using the following nomenclature: M-12 M-14/1 0-6", M-12 M-14/1 6"-12" to M-12 M-14/11 0-6", M-12 M-14/11 6"-12". The samples were analyzed for PCBs utilizing USEPA Method 8082.

4.1 Chemical Characterization

The sediment laboratory analytical data were compared to the established screening level criteria, as presented in the *NJDEP Guidance for Sediment Quality Evaluations* (November 1998). This evaluation included at least two samples from each boring to assess the sampling data and to identify potential contaminants of concern. For marine/estuarine sediment screenings, the guidelines define two guidance concentrations for Total PCBs, an Effects Range-Low (ER-L) and an Effects Range-Medium (ER-M). The ER-L (0.023 mg/kg Total PCBs) represents the concentration at which adverse benthic effects are found in approximately 10% of studies. The ER-M (0.180 mg/kg Total PCBs) represents the concentration at which a greater than 50% incidence of adverse effects to sensitive species and/or life stages is likely to occur. The ER-L and ER-M are not regulatory cleanup standards. An exceedence indicates a potential risk to the benthic community and helps determine the need for further investigations (e.g., toxicity testing, tissue bioassays, etc.). However, an exceedence of the ER-L/ER-M criteria does not necessarily mandate further investigations if the sediments proximal to the Site have similar contaminant concentration ranges to upgradient sediments. As stated previously, the samples were collected beginning with the downstream location (B-1) and proceeding to the upstream location (B-11). Therefore, the upgradient sediments are most closely represented by the laboratory data for location B-11 (see **Table 4-1**). No PCBs were detected in sediment samples collected at this location.

Based on the *NJDEP Guidance for Sediment Quality Evaluations* (November 1998), the Lowest Effects Levels (LEL) and the Severe Effects Levels (SEL) are to be used as guidelines for individual Arochlors. Arochlor 1254 is the only Arochlor found at the Landfill Sites shown on **Figure 2-3**. The LEL indicates concentrations at which adverse benthic impacts may begin to occur (level tolerated by most benthic organisms). The SEL is a contamination level that indicates severe impacts to the benthic community in most cases studied. Both the LEL and the SEL are derived from freshwater sediment screening criteria; however, they are used in conjunction with the marine/estuarine ER-L and ER-M values for screening purposes. The ER-L and ER-M apply to Total PCBs, whereas the LEL and SEL can be used for screening purposes for individual Arochlors.

In the case of non-polar organic compounds, such as PCBs, it may be necessary to modify the SEL to create a Site-specific SEL (SSEL) based on the Total Organic Carbon (TOC) fraction present in the sample. The TOC fraction is used to determine if the samples were collected in depositional zones, evidenced by a higher percentage of fine-grained particles. Depositional zones are generally the areas of highest potential contamination and are targeted during Site sampling events. To calculate a SSEL, the SEL is multiplied by the TOC fraction. If the TOC of the samples is not measured during sampling, as is the case at the M-12/M-14 Site, a default value of 1% is used. In this instance, each SEL is multiplied by 0.01 to derive the SSEL for comparison purposes. At M-12/M-14, no Arochlors were detected. However, at other Fort Monmouth Landfill Sites, the only Arochlor detected in the sediments was Arochlor 1254. The LEL, SEL and SSEL for Arochlor 1254 are shown below.

Polychlorinated Biphenyl	LEL (mg/kg, dry weight)	SEL (mg/kg organic carbon, dry weight)	SSEL (mg/kg)
Arochlor 1254	0.060	34	0.34

mg/kg=milligrams per kilogram

The USEPA, Region II, and the NJDEP Bureau of Environmental Evaluation and Risk Assessment/Environmental Toxicology and Risk Assessment (BEERA/ETRA) have discontinued the SSEL approach for general screening purposes except in cases of borderline screening exceedances and/or a weight of professional evidence suggesting that the SSEL is appropriate. The SSEL approach is discussed here for completeness, but was not otherwise used to formulate Site-related environmental risk decisions or conclusions.

The results of the PCB laboratory analysis indicated one detection above the laboratory MDL in the duplicate sample of M12M14/9 0-6". This detection is likely to be an anomalous result because PCBs were not detected in M12M14/9 0-6". Additionally, the result appears to be an isolated occurrence because no other upgradient landfill sites (M-3, M-4 and M-5) have presented similar PCB exceedances.

This sample result exceeds both the NJDEP Effects Range – Low (ER-L) and Effects Range – Medium (ER-M) guidance concentrations for Total PCBs (0.023 mg/kg and 0.180 mg/kg, respectively). The ER-L and ER-M represent the concentrations at which adverse benthic effects are found in approximately 10% and 50% of studies, respectively. This sample also exceeds the Arochlor 1254 (the only Arochlor detected at the Site) LEL of 0.060 mg/kg, the concentration at which adverse benthic impacts may begin to occur (the level tolerated by most benthic organisms). The PCB detection did not exceed the SSEL for Arochlor 1254 (0.34 mg/kg). As such, this result, if not anomalous, is unlikely to result in long-term adverse benthic effects in Husky Brook.

Due to the presence of only one potentially anomalous result that did not exceed the SSEL for Arochlor 1254, no potential exists for long-term adverse benthic effects in Husky Brook associated with the M-12/M-14 Landfill Site.

The sample results are summarized in **Table 4-1: PCB Sample Results Summary – M-12/M-14 Landfill Site**. The laboratory data sheets are available in **Appendix D**.

4.2 QA/QC

In order to verify the reliability of the analytical results, Versar reviewed the holding times for each sample and the results of the analysis of two field duplicate samples. All samples were analyzed by the FMETL within the prescribed holding time requirements for each analytical method.

Two field duplicate samples were collected during the Site sampling events to verify the consistency of the entire sampling and analysis procedure. The results for the two duplicate samples were close to those obtained for the original samples. The relative percent difference (RPD) was calculated for each duplicate sample. The RPD measures variability introduced by both the laboratory and field operations. The RPD for the duplicate samples was 175.6%. This RPD exceeds the established limit of 50% for laboratory duplicate samples. However, this is due to low sample concentrations and a correspondingly low MDL used by the laboratory and is not indicative of poor precision because the differences noted may be attributed to analytical sensitivity. Also, the comparison of one very small number with another very small number will result in a high RPD.

5.0 CONCLUSIONS

Based on the results of this sediment quality evaluation, no PCBs were detected above the NJDEP guidance criteria for sediment quality in any sample, and no potential exists for long-term adverse benthic effects in Husky Brook associated with the M-12/M-14 Landfill Site. Therefore, No Further Action is recommended for the M-12/M-14 Landfill Site related to potential PCB impacts to the sediments of Husky Brook.

Re: Sediment Sampling Plan
Sites M-2, M-3, M-4, M-5, M-8, M-12, M-14, M-18 and CW-3A
Fort Monmouth Main Post/Charles Wood
Tinton Falls, Monmouth County

Dear Mr. Fallon:

The NJDEP has reviewed the March 29, 2000 Sediment sampling plan for the nine former landfill sites referenced above and we accept the plan as submitted.

The referenced document, developed with NJDEP using appropriate technical guidance documents and requirements, is specifically designed to determine if PCBs have impacted adjacent surface waters.

There are a few brief comments which we have previously discussed, but I wanted to note here as a reminder for you in this investigation.

- The NJDEP requires PCB method 8082 to be utilized.
- Approved sample preservation methods must be used if volatile compounds are to be investigated or reported on.
- Some discussion regarding the sediment criteria utilized along with a discussion on the application to the sample location and water body must be provided in the final report.
- Sampling must be performed on downgradient samples first.

If you should have any questions or comments, please do not hesitate to contact me at (609) 633-7232 or via E-mail.

Sincerely,

Ian R. Curtis, Case Manager
Bureau of Case Management
ICURTIS@DEP.STATE.NJ.US

Re: Sediment Sampling Plan for Nine Former Landfill Sites
(i.e. M-2, M-3, M-4, M-5, M-8, M-12, M-14, M-18 & CW-3A)
Main Post and Charles Wood Area, Fort Monmouth, New Jersey

Dear Mr. Curtis:

Submitted for your review and approval, please find a copy of the above referenced sampling plan. Said plan should enable the Directorate of Public Works to ascertain whether polychlorinated biphenyls are present within stream sediments bordering the nine referenced landfills. Future site work will be based upon the findings of this sampling initiative.

Should you have any questions or require any additional information regarding this plan, please contact the undersigned at the following telephone number: (732) 532-6223.

Sincerely,

Joseph M. Fallon

1.0 SAMPLING ACTIVITIES

1.1 OVERVIEW

This report provides details for a proposed sediment sampling plan as prepared by TECOM-Vinnell Services (TVS) on the behalf of the U.S. Army Fort Monmouth, Directorate of Public Works (DPW), Fort Monmouth, New Jersey. The purpose of this sampling initiative is to ascertain whether Polychlorinated Biphenyls (PCBs) are present within stream sediments which border nine former landfill sites (i.e. M-2, M-3, M-4, M-5, M-8, M-12, M-14, M-18 and CW-3A). The streams associated with this investigation include Mill Creek, Lafetra Creek, Parkers Creek, Husky Brook, and an unnamed tributary of Wampum Brook (see attachments 1 & 2). The data generated from this study will be used in conjunction with other previously collected data involving surface soils, subsurface soils, ground water and surface water. As part of the larger, ongoing remedial investigation at these nine landfill sites, PCBs were identified within subsurface soils at landfill sites M-2 and M-8. The Final Site Investigation (SI) Report, Fort Monmouth, New Jersey, Main Post and Charles Wood Areas (December 1995) identifies electronic components as one of the waste types being disposed of within the subject landfills. Said components (i.e. electrical ballasts) typically contained small quantities of insulating oil which may or may not have contained PCBs. Based upon the potential presence of electronic components at the other seven landfill sites, PCBs may also exist within subsurface soils at these locations. As part of previously conducted sampling initiatives, the DPW has been able to document that the PCBs identified at sites M-2 and M-8 have not impacted site ground water or surface water. Furthermore, PCBs have not been identified within site ground water or surface water at the other landfill sites. The overall goal of the proposed sampling plan is to document that the presence of PCBs at sites M-2 and M-8 have not impacted the nearby stream sediments.

This investigation will be conducted by TVS personnel in accordance with the specifications required for collecting sediment samples as determined by the New Jersey Department of Environmental Protection (NJDEP) Field Sampling Procedures Manual (May 1992) and the NJDEP Guidance For Sediment Quality Evaluations (November 1998).

1.2 SITE DESCRIPTION

Mill Creek is located along the northern side of the M-2 landfill (approximate distance 1,400 feet) and along the western side of the M-4 landfill (approximate distance 360 feet) and the M-5 landfill (approximate distance 570 feet). Lafetra Creek runs along the northern side of the M-3 landfill (approximate distance 1,200 feet), joining with Mill Creek to form Parkers Creek. Parkers Creek surrounds the M-8 landfill (approximate distance 1,500 feet) on the western, northern, and eastern sides. It then runs along the western side of the M-18 landfill (approximate distance 700 feet). Husky Brook runs along the northern side of the M-12 landfill, eventually running between the M-12 and M-14 landfills (combined approximate distance 1,700 feet) before flowing into Oceanport Creek. An unnamed tributary of Wampum Brook is located along the northern side of the CW-3A landfill (approximate distance 600 feet). Stream banks along the landfills vary from heavily vegetated with trees and bramble to simply grass. A stream bank restoration project is currently underway at the landfill sites located on the Main Post. The project entails stabilizing the stream banks through a combination of hard (rip-rap) and soft (vegetative plantings) engineering practices. All sites vary in steepness and have various access points. The streams flow constantly even in drought conditions and all but the unnamed tributary of Wampum Brook are tidally influenced. Currents and depth vary with tide.

1.3 HEALTH AND SAFETY

Before sampling activities commence, potential site hazards (physical, chemical and biological) will be evaluated by the TVS Health and Safety Office. A site specific Health and Safety Plan shall be prepared accordingly.

2.0 SITE INVESTIGATION ACTIVITIES

2.1 CONTACTS AND PERSONNEL

The following is a listing of all contacts and personnel involved in the investigation. All analyses are to be performed and reported by U.S. Army Fort Monmouth Environmental Laboratory, NJDEP- Certification # 13461. All sampling will be performed under the direct supervision of a NJDEP trained sample technician according to the methods described in the NJDEP Field Sampling Procedures Manual (1992) and as defined in this sampling plan.

The following parties are participants in this investigation:

- Environmental Protection Specialist: Joseph Fallon, CHMM
  Employer: U.S. Army, Fort Monmouth Phone Number: (732) 532-6223
- Field Technician: Corey McCormack
  Employer: TECOM-Vinnell Services (TVS) Phone Number: (732) 532-0989
- Analytical Laboratory: U.S. Army Fort Monmouth Environmental Laboratory
  Contact Person: Daniel Wright - Phone Number: (732) 532-4359
  Employer: TECOM-Vinnell Services
  NJDEP Certification No.: 13461
- Field Technician Supervisor: Mark Laura
  Employer: TECOM-Vinnell Services (TVS) Phone Number: (732) 532-0989
- Health and Safety Personnel: Bruce Wadlington, Chandra Jennings, and John Wierbowski. Employer: TVS - Phone Number: (732) 532-1706

2.2 SAMPLING PROCEDURES AND PROTOCOL

During the investigation, all samples will be collected with proper attention to quality assurance protocols and in accordance with the guidelines set forth by the New Jersey Department of Environmental Protection (NJDEP) Field Sampling Procedures Manual (May, 1992), the Technical Requirements for Site Remediation (NJAC 7:26E, June, 1993) and the NJDEP Guidance for Sediment Quality Evaluations (November 1998).

2.2.1 SITE ACTIVITES

Site activities shall include recording field conditions and other relevant observations, sampling sediments, plotting sample locations by usc of our Global Positioning Systcm (GPS), decontamination of equipment, and preservation and storage of samples.

2.2.2 SEDIMENT SAMPLING

Sample locations will be determined, sampled, and recorded in the following way:

1. Samples will be taken from clearly discernable depositional areas in and along the streams. In the event that no clear depositional areas can be located, a sample will be taken from the best possible stream bed point at the rate of 1 sample for every 100 feet.
2. Samples will be taken at a depth of 0-6 inches for surface deposits and 6-12 inches for subsurface deposits in each sampling event. Based upon the individual thickness of each depositional area, an 18-24 inch deep sample will also be taken if the desired depth is obtainable.
3. Sampling will commence from downstream, working upstream. Care will be taken to minimize disturbance of sediments and washing of samples as collected.
4. Tide, weather, recent activity, and notable observations will be recorded.
5. A boring log shall be created to note any layers, particle sizes, and defining aspects to each boring.
6. Sampling will be conducted using a hand core sediment sampler.
7. Samples for PCBs analysis will be collected into new, pre-cleaned, 4oz.clear glass jars with Teflon lined caps. All samples will be stored in a cooler at 4 degrees Celsius.
8. After each sampling event, equipment will be decontaminated as stated in section 2.3.
9. Each sample location will be plotted using our GPS.

2.2.3 QA/QC

Quality control samples are required to verify that the sample collection and handling process has not affected the quality of the sediment samples. All field quality control samples will be prepared exactly as regular investigation samples with regard to volume and containers. The following quality control samples will be collected for each batch of samples:

- Field duplicate daily or one every 20 samples; homogenized before splitting.

2.3 EQUIPMENT DECONTAMINATION

Decontamination will be done after every sampling event by the following procedure:

1. Alconox and water wash
2. Water rinse
3. Deionized water rinse
4. Air dry

Landfill Stream Sediment PCB's Sample Event Site Field Summary for M12/M14

Husky Brook runs along the northern side of the M12 landfill, eventually running between M12 and M14 landfills (approximately 1700 feet total) before flowing out into Oceanport Creek.

This stream has had all the lower portions of bank on both landfill sides worked on as part of the stream bank restoration project. Previously the banks were just grass covered here, exposed and eroding away into the brook. It currently is covered with large rock and rip-rap. There is little debris in the stream itself in the lower portion.

Further upstream, it is a mixed bank of tree, bramble, and smaller vegetation. There are man made materials and garbage on the banks and in the streambed here. Most materials are old poles, and rail ties. Some lighter restoration work has been done.

Flow is constant, and depth varies with tide. Even at low tide there are pools 3-4 feet deep. Most occur in the lower portion of the brook. The weather at time of sampling was cold, and sunny. There was a rain/snow event a day prior to the sampling. Tide was low.

Depositional areas are scattered here as well. Sampling targeted these areas. When none were available, 1 sample per 100 feet was taken.

EXECUTIVE SUMMARY

VERSAR, Inc. (VERSAR) has been contracted by the United States (U.S.) Army Installation, Fort Monmouth (Fort Monmouth), Directorate of Public Works (DPW), Fort Monmouth, New Jersey, to prepare a Remedial Investigation Report (RIR) for data collected during recent sediment sampling events at the M-12/M-14 Landfill Sites (Site). This report describes the remedial investigation activities conducted at the Site on April 10, 2000.

The Site is located on the Main Post Area of Fort Monmouth on the north and south side of Husky Brook, west of Murphy Drive, and occupies approximately 9.0 acres. The Site is comprised of both the M-12 and the M-14 landfills. The M-12 landfill consists of two separate areas, a northeast area and a southwest area. According to the Roy F. Weston (WESTON) report, *Site Investigation, Fort Monmouth, New Jersey, Main Post and Charles Wood Areas, Site Investigation Report (December 1995)*, both landfills were historically used for the disposal of domestic and industrial wastes. In the 1995 Site Investigation (SI), WESTON conducted a geophysical survey, groundwater sampling and tidal monitoring at each landfill. In addition, surface water samples were obtained from the portion of Husky Brook that is adjacent to the M-14 landfill. WESTON recommended that a long-term groundwater monitoring program be developed and implemented at the M-12 and M-14, but provided no recommendations related to Site-specific sediment quality. A long-term surface water monitoring program was also recommended for M-14.

Other studies conducted at similar Main Post Landfill sites (M-2 and M-8) found polychlorinated biphenyl (PCB) -containing materials (e.g., electrical ballasts) disposed of in each landfill. In addition, PCBs were detected in soil and/or groundwater at both the M-2 and M-8 Landfill sites. Therefore, assuming that other landfills on the Main Post had received similar waste materials, the DPW initiated a sediment sampling investigation in the second quarter of 2000 to evaluate potential impacts to stream sediments in creeks and/or brooks running adjacent to the Main Post and Charles Wood (CW-3A only) landfill sites. The M-12/M-14 Landfill Site was included in the sediment sampling program to supplement the WESTON findings related to soil, surface water and groundwater matrices.

To determine potential PCB-related impacts to sediments in Husky Brook, the DPW obtained 25 sediment samples on April 10, 2000, including two duplicate samples for quality assurance/quality control (QA/QC), from the surface and near-surface sediments of Husky Brook. The samples were obtained along the 1,700-foot portion of Husky Brook that flows through the M-12/M-14 Site. All 25 sediment samples were analyzed for PCBs and compared to the sediment sampling guidance concentrations defined in the New Jersey Department of Environmental Protection (NJDEP) *Guidance for Sediment Quality Evaluations (November 1998).* The analytical data is summarized in table form in this RIR. VERSAR developed this RIR based on the evaluation of these sediment data.

Data presented in Section 3.0 of this RIR indicate that there was one anomalous detection of PCBs in a duplicate sample but that no PCBs were detected in any of the 25 samples obtained from Husky Brook. Based on NJDEP guidance criteria, the results indicate that there are no PCB-related impacts to sediments in Husky Brook, which flows through the M-12/M-14 Landfill Site.

Based on the results of this sediment quality evaluation, no PCBs were detected above the NJDEP guidance criteria for sediment quality in any sample, and no potential exists for long-term adverse benthic effects in Husky Brook associated with the M-12/M-14 Landfill Site. Therefore, No Further Action is recommended for the M-12/M-14 Landfill Site related to potential PCB impacts to the sediments of Husky Brook.

1.0 INTRODUCTION

VERSAR has been contracted by the U.S. Army Installation, Fort Monmouth, DPW, Fort Monmouth, New Jersey to prepare an RIR and sediment quality evaluation for the Site located at the Fort Monmouth Main Post Area. This report addresses the remedial investigation activities performed at the Site on April 10, 2000.

1.1 Objectives

Other studies conducted at similar Main Post Landfill sites (M-2 and M-8) found PCB-containing materials (e.g., electrical ballasts) disposed of in each landfill. In addition, PCBs were detected in soil and/or groundwater at both the M-2 and M-8 Landfill sites. Therefore, assuming that other landfills on the Main Post had received similar waste materials, the DPW initiated a sediment sampling investigation in the second quarter of 2000 to evaluate potential impacts to stream sediments in creeks and/or brooks running adjacent to the Main Post and Charles Wood (CW-3A only) landfill sites. The M-12/M-14 Landfill Site was included in the sediment sampling program to supplement the earlier WESTON findings related to the soil, surface water and groundwater matrices.

The objective of this RIR is to determine potential PCB-related impacts to stream sediments in Husky Brook, which flows through the M-12/M-14 Landfill Site. The remedial investigation was conducted in accordance with New Jersey Administrative Code (NJAC) 7:26E - *Technical Requirements for Site Remediation* (February 2003) and NJDEP *Guidance for Sediment Quality Evaluations* (November 1998).

The remedial investigation encompassed the following:

- Obtaining surface and near-surface sediment samples approximately every 100 feet along the bottom of Husky Brook, which flows through the M-12/M-14 Landfill Site.
- Analyzing the samples for PCBs by United States Environmental Protection Agency (USEPA) Method 8082.
- Comparing the analytical results to the screening level criteria defined in the NJDEP *Guidance for Sediment Quality Evaluations* (November 1998).

1.2 Report Organization

This report is organized to minimize repetition. **Section 2.0** provides background information and a general description of the M-12/M-14 Landfill Site located at the Fort Monmouth Main Post area. **Section 3.0** describes and summarizes the sampling procedure and activities. **Section 4.0** presents analytical results and compares those results with NJDEP guidance criteria. **Section 5.0** provides a summary of the findings of the remedial investigation, and requests a No Further Action determination from the NJDEP.

2.0 SITE BACKGROUND AND ENVIRONMENTAL SETTING

The following sections describe the Site background and environmental setting of the area surrounding Fort Monmouth and the M-12/M-14 Landfill Site. Included is a description of the Site location, background, current conditions and environmental setting.

2.1 Site Location and Description

Fort Monmouth is located in the central-eastern portion of New Jersey in Monmouth County, approximately 45 miles south of New York City and 70 miles northeast of Philadelphia (**Figure 2-1**). In addition to the Main Post, the installation includes two subposts, the Charles Wood Area and the Evans Area. The Main Post encompasses approximately 630 acres and is generally bounded by State Highway 35, Parkers Creek, Lafetra Creek, the New Jersey Transit Railroad and a residential area to the south. The post was established in 1918 during World War I (WWI) as an Army Signal Corps training center. The Main Post currently provides administrative, training, and housing support functions, as well as providing many of the community facilities for Fort Monmouth. The primary mission of Fort Monmouth is to provide command, administrative, and logistical support for Headquarters, U.S. Army Communications and Electronics Command (CECOM). CECOM is a major subordinate command of the U.S. Army Materiel Command (AMC) and is the host tenant at Fort Monmouth.

The M-12/M-14 Landfill Site is located on the north and south sides of Husky Brook, west of Murphy Drive, in the Main Post Area (**Figure 2-2**). The approximate area of the M-12/M-14 Landfill Site is 389,300 feet^2 (9.0 acres). The M-12 landfill consists of two areas, a northeast area and a southwest area. Husky Brook flows along the northern boundary of the M-14 landfill and eventually between both the M-12 and M-14 landfills, for a distance of approximately 1,700 feet. It ultimately flows into Oceanport Creek. The bank of Husky Brook contains trees, bramble and small vegetation upstream and large rocks downstream. Portions of Husky Brook have been repaired/restored as part of a streambank Landfill project.

The various Landfill Sites on the Main Post are identified on **Figure 2-3**. The map is provided to identify:

- the relative location of each of the former landfill sites due to the similarity of past site uses, the types debris deposited at these locations, and the nature of the contaminants identified in soil, groundwater and/or sediment samples during the present and former investigations; and
- the proximity and interrelatedness of the adjacent surface water bodies.

2.2 Site Background

The WESTON report, *Site Investigation, Fort Monmouth, New Jersey, Main Post and Charles Wood Areas, Site Investigation Report* (December 1995), summarized surface

water sampling events that have been conducted since February 1986 for samples collected in Husky Brook. These sampling events were part of a former New Jersey Pollutant Discharge Elimination System (NJPDES) Permit and were obtained in that portion of Husky Brook that flows along the northern border of the M-14 landfill. From these sampling events, a report prepared by WESTON in 1993 (*Investigation of Suspected Waste Sites at Fort Monmouth, New Jersey*) indicates that no compounds were detected above NJDEP surface-water criteria.

The WESTON SI Report (WESTON, 1995) summarizes the results of a geophysical survey for determining landfill boundaries, groundwater sampling and tidal monitoring. In addition, surface-water samples were obtained in that portion of Husky Brook flowing along the northern boundary of the M-14 landfill. The surface water samples were sampled for volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides, PCBs and TAL metals. According to the WESTON SI report, VOCs, SVOCs, pesticides and PCBs were not detected above laboratory method detection limits (MDLs) in the samples. For the TAL metals analysis, no metals were detected at concentrations above NJDEP surface water criteria. The WESTON SI report recommended the implementation of a long-term groundwater monitoring program due to the historical Site use as a landfill. The present investigation was undertaken to further expand the WESTON SI report and assess the potential PCB-related impacts to stream sediments based on past Site use.

2.3 Current Conditions

VERSAR conducted a site walk on December 11, 2000 to assess current conditions at the M-12/M-14 Landfill Site. The M-12 site consists of two areas separated by a tributary to Husky Brook, which is bounded by trees and shrubs. The western M-12 area was recently backfilled and graded with black fill material. There was no vegetation present at the time of the Site walk, with the exception of areas along Husky Brook on the north side of the site, which was bounded with trees. The eastern portion of the M-12 site was an open field of grass.

M-14, located on the north side of Husky Brook, consists of an open field with some trees. This area was landscaped, with the grass cut and the trees pruned. On the eastern side of the Site is a playground. Site photographs are provided in **Appendix A**.

2.4 Environmental Setting

The following is a description of the geological/hydrogeological setting of the area surrounding the M-12/M-14 Landfill Site. Included is a description of the regional geology and hydrogeology of the area surrounding Fort Monmouth, as well as descriptions of the local geology and hydrogeology of the M-12/M-14 area.

2.4.1 Regional Geology

Monmouth County lies within the New Jersey Section of the Atlantic Coastal Plain physiographic province. The M-12/M-14 Landfill Site is located in what may be referred to as the Outer Coastal Plain subprovince, or the Outer Lowlands. The geologic map of New Jersey is provided as **Figure 2-4**.

In general, New Jersey Coastal Plain formations consist of a seaward-dipping wedge of unconsolidated deposits of clay, silt, sand and gravel. These formations typically strike northeast-southwest with a dip ranging from 10 to 60 feet per mile and were deposited on Precambrian and lower Paleozoic rocks (Zapecza, 1989). These sediments, predominantly derived from deltaic, shallow marine, and continental shelf environments, date from Cretaceous through the Quaternary Periods. The mineralogy ranges from quartz to glauconite.

The formations record several major transgressive/regressive cycles and contain units, which are generally thicker to the southeast and reflect a deeper water environment. More than 20 regional geologic units are present within the sediments of the Coastal Plain. Regressive, upward coarsening deposits are usually aquifers (e.g., Englishtown and Kirkwood Formations, and the Cohansey Sand), while the transgressive deposits act as confining units (e.g., the Merchantville, Marshalltown and Navesink Formations). The individual thickness for these units varies greatly (e.g., from several feet to several hundred feet). The Coastal Plain deposits thicken to the southeast from the Fall Line (e.g., a boundary zone between older, resistant rocks and younger, softer plain sediments) to greater than 6,500 feet in Cape May County (Brown and Zapecza, 1990).

Based on the regional geologic map (Jablonski, 1968), the Cretaceous age Red Bank and Tinton Sands outcrop at the Main Post Area. The Red Bank Sand conformably overlies the Navesink Formation and dips to the southeast at 35 feet per mile. The upper member (Shrewsbury) of the Red Bank Sand is a yellowish-gray to reddish brown clayey, medium-to-coarse-grained sand that contains abundant rock fragments, minor mica and glauconite (Jablonski). The lower member (Sandy Hook) is a dark gray to black, medium-to-fine grained sand with abundant clay, mica and glauconite.

The Tinton Sand conformably overlies the Red Bank Sand and ranges from a clayey medium to very coarse-grained feldspathic-quartz and glauconite-sand to a glauconitic-coarse sand. The color varies from dark yellowish orange or light brown to moderate brown and from light olive to grayish olive. Glauconite may constitute 60 to 80 percent of the sand fraction in the upper part of the unit (Minard, 1969). The upper part of the Tinton is often highly oxidized and iron oxide encrusted (Minard, 1969).

The Kirkwood Formation (part of the Kirkwood-Cohansey system) crops out southeast of the Main Post and dips to the southeast at a slope of 20 feet per mile (Jablonski, 1968). The Kirkwood Formation consists of alternating layers of sand and clay. The upper unit is a light gray to yellowish-brown, fine-grained quartz sand with quartz nodules and small pebbles. The lower unit is a brown silt in Monmouth County (Jablonski, 1968).

2.4.2 Regional Hydrogeology

Fort Monmouth lies in the Atlantic and Eastern Gulf Coastal Plain groundwater region (Meisler et al., 1988). This groundwater region is underlain by undeformed, unconsolidated to semi-consolidated sedimentary deposits. The chemistry of the water near the surface is variable with low dissolved solids and high iron concentrations. The water chemistry in areas underlain by glauconitic sediments (such as Red Bank and Tinton Sands) is dominated by aluminum, calcium, magnesium, manganese and iron. The sediments in the area of Fort Monmouth were deposited in fluvia-deltaic to nearshore environments.

The water table aquifer in the Main Post area is identified as part of the "composite confining units," or minor aquifers. The minor aquifers include the Navesink formation, Red Bank Sand, Tinton Sand, Hornerstown Sand, Vincentown Formation, Manasquan Formation, Shark River Formation, Piney Point Formation and the basal clay of the Kirkwood Formation.

Well records indicate that wells installed in the Red Bank and Tinton Sands produce 2 to 25 gallons per minute (gpm). Water in these upper hydrogeologic units is typically encountered at shallow depths below ground surface (2 to 9 feet bgs). However, domestic wells are generally screened deeper in these upper hydrogeologic units. The shallow water table conditions in the Tinton and Red Bank Sands, and the similar composition of these sands within the Kirkwood Formation, suggest that the Tinton-Red Bank-Kirkwood sequence forms a single, laterally continuous aquifer. Water in this water-table aquifer flows east toward the Atlantic Ocean. Local topography tends to deflect the flow toward local depressions.

As stated in the SI Report (WESTON, 1995), NJAC 7:9-6, *Groundwater Quality Standards* (GWQS) establishes groundwater quality criteria for different classes of groundwater. Class II-A, which is defined as all groundwater that is not classified as one of the other special classes, is the appropriate class for groundwater at Fort Monmouth. The primary designated use for Class II-A groundwater is potable water; secondary uses include agricultural and industrial water.

Shallow groundwater is locally influenced within the Main Post Area by the following factors:

- Tidal influence (based on proximity to the Atlantic Ocean, rivers and tributaries)
- Topography
- Nature of the fill material within the Main Post Area
- Presence of clay and silt lenses in the natural overburden deposits
- Local groundwater recharge areas (e.g., streams, lakes)

Due to the fluvial nature of the overburden deposits (e.g., sand and clay lenses), shallow groundwater flow direction is best determined on a case-by-case basis. The groundwater

flow in the vicinity of the M-12/M-14 Landfill Site is assumed to be to the north for the M-12 landfill, in the direction of Husky Brook, and south for the M-14 landfill, also towards Husky Brook.

2.4.3 Local Geology/Hydrogeology

As presented in the WESTON SI, the field logs from monitoring well installations indicate that the lithology at M-12/M-14 consists of a thin soil cover (0.3 feet) underlain by fill material. The components of the fill materials observed in the borings consisted of organic debris and coal fragments intermixed with a moderate to poorly sorted olive-green-brown silty medium-fine-grained sand with little clay. Groundwater saturation was observed at approximately 2 feet bgs across the site. Water-level elevation data collected during the WESTON SI indicate that local groundwater flow is west toward Husky Brook.

2.4.4 Soils

According to the U.S. Department of Agriculture (USDA), Soil Conservation Service, Monmouth County Soil Survey, the majority of the Main Post area is covered by urban land (**Figure 2-5**). The soil survey described urban land as areas where concrete, asphalt, buildings, shopping centers, airports or other impervious surfaces cover 80 percent or more of the surface. In addition, the survey indicated that the natural subsurface soils have largely been replaced with artificial or foreign fill materials (developed land with disturbed soils). The following soil series and classification units are mapped in the Main Post Area:

- DoB Downer sandy loam (with 2 to 5 percent slopes);
- FrB Freehold sandy loam (with 2 to 5 percent slopes);
- FUB Freehold sandy loam/urban land complex (with 0 to 10 percent slopes);
- HV Humaquepts, frequently flooded;
- KvA Kresson loam (with 0 to 5 percent slopes);
- UA Udorthents, smoothed; and
- UD Udorthents – urban land complex (with 0 to 3 percent slopes).

The Downer series soils are well-drained soils that are found on uplands and terraces. The soils are formed in acid, silty coastal plain sediments. The Freehold soils are also well drained and are formed in acid, loamy, coastal plain sediments that, by volume, are 1 to 10 percent glauconite and are found on uplands. The Humaquepts soils are somewhat poorly- to very poorly- drained soils that are formed in stratified, sandy, or loamy sediments of fluvial origins. The Humaquepts soils are located on the floodplain and are subject to flooding several times each year. The Kresson loam is a nearly level to gently sloping soil and is somewhat poorly drained. The soil is found on low divides and in depressions. The Udorthents soils have been altered by excavation or filling activities. In filled areas, these soils consist of loamy material that is more than 20 inches thick. The filled areas include floodplain, tidal marshes and areas with moderately, well drained to very poorly drained soils. Some Udorthent soils contain concrete, asphalt, metal and

glass. The soils in the vicinity of the M-12/M-14 Landfill Site are classified as UA to UD, Udorthents, smoothed to Udorthents, urban land complex.

2.4.5 Topography and Surface Drainage

Over the last 80 years, the natural topography of Fort Monmouth has been altered by excavation and filling activities by the military. The M-12/M-14 Landfill Site is located on the floodplain of Husky Brook. The USGS topographic map (**Figure 2-1**) shows that the land surface of the Site is relatively flat at an elevation of less than 20 feet above mean sea level (amsl).

Surface water bodies from the western part of the Main Post flows into the Lafetra Creek to the north or into the Mill Creek to the south. The USGS topographic map (**Figure 2-1**) shows the Lafetra Creek as Parkers Creek Branch and Mill Creek as Wampum. Both Mill and Lafetra Creek originate off-post. Mill Creek flows along the southern boundary of the Main Post, turning north just past the Auto Craft Shop. Mill Creek is channelized and flows past the north side of the M-2 Landfill. Lafetra Creek forms the northern boundary of the Main Post and joins Mill Creek to form Parkers Creek. Parkers Creek flows eastward along the northern boundary and joins Oceanport Creek east of the post. Most of Parkers Creek, Lafetra Creek and Mill Creek are tidally influenced.

The U.S Fish and Wildlife Service (FWS) National Wetland Inventory Long Branch quadrangle maps indicate the presence of wetlands at the Main Post. Parkers and Oceanport Creeks are classified as estuarine intertidal aquatic beds. The area of Parkers Creek and the part of Oceanport Creek/Husky Brook are classified as estuarine intertidal emergent wetlands. Lafetra Creek and Mill Creek are classified as riverine lower perennial open water/unknown bottom.

3.0 SEDIMENT SAMPLING ACTIVITIES

Fort Monmouth DPW conducted sediment sampling in Husky Brook to evaluate potential PCB-related impacts to stream sediments associated with the M-12/M-14 Landfill Site. On April 10, 2000, 11 borings were installed approximately every 100 feet along the bottom of Husky Brook, as shown in **Figure 3-1: M-12/M-14 Boring Location Map.** The locations extended from downstream at Boring B-1 near Murphy Drive to upstream at Boring B-11, and were sampled accordingly in that order (see chain-of-custody records, **Appendix D**). The sediment sampling was conducted in accordance with the *Installation Restoration Program Sediment Sampling Plan for Nine Former Landfill Sites* (TVS, March 2000) presented in **Appendix B**. The Sediment Sampling Plan (SSP) was approved by the NJDEP on April 3, 2000.

Twenty-five sediment samples were collected, including two duplicate samples for QA/QC, from 11 borings using a Wildco Sediment Sampler. The samples were obtained along the 1,700-foot portion of Husky Brook that flows through the Site. Sample depths ranged from surface (0 to 6 inches) to near-surface (6 inches to 12 inches below grade) at each boring location, with the exception of Borings B-1, B-4 and B-6, which were also sampled at a depth of 18 inches to 24 inches below grade. The samples consisted of black to brown fine sandy silt to green/black clay and sandy clay with black bands, some organic material and small angulars. Boring logs are provided in **Appendix C**.

Sampling equipment was thoroughly decontaminated before and after each use, in accordance with the SSP. The sediment samples were collected using a Wildco Sampler and immediately placed in laboratory-supplied bottleware. The sample containers were labeled, sealed, packed in ice and transported to the Fort Monmouth Environmental Testing Laboratory (FMETL), New Jersey Certification Number NJDEP 13461, under proper chain-of-custody procedures. The samples were analyzed by FMETL on April 10, 2000 for PCBs utilizing USEPA Method 8082. Copies of the chain-of-custody for the laboratory analysis can be found in **Appendix D**. A summary of the borings, including sample IDs, sample collection date/time, sample depths, northing/easting coordinates, analysis and general soil descriptions is provided in **Table 3-1: Sediment Sample Summary**.

4.0 SITE CHEMICAL CHARACTERIZATION

On April 10, 2000, DPW collected 25 sediment samples along the bottom of Husky Brook to evaluate potential PCB-related impacts to stream sediments from the adjacent M-12/M-14 Landfill Site. Eleven borings were installed at the approximate rate of one per 100 feet along the bottom of the brook. Twenty-five samples were collected from 11 borings at depths ranging from surface (0 to 6 inches) to near-surface (6 inches to 12 inches below grade) at each boring location with the exception of Borings B-1, B-4 and B-6, which were also sampled at a depth of 18 inches to 24 inches below grade. Samples were identified in the field using the following nomenclature: M-12 M-14/1 0-6", M-12 M-14/1 6"-12" to M-12 M-14/11 0-6", M-12 M-14/11 6"-12". The samples were analyzed for PCBs utilizing USEPA Method 8082.

4.1 Chemical Characterization

The sediment laboratory analytical data were compared to the established screening level criteria, as presented in the *NJDEP Guidance for Sediment Quality Evaluations* (November 1998). This evaluation included at least two samples from each boring to assess the sampling data and to identify potential contaminants of concern. For marine/estuarine sediment screenings, the guidelines define two guidance concentrations for Total PCBs, an Effects Range-Low (ER-L) and an Effects Range-Medium (ER-M). The ER-L (0.023 mg/kg Total PCBs) represents the concentration at which adverse benthic effects are found in approximately 10% of studies. The ER-M (0.180 mg/kg Total PCBs) represents the concentration at which a greater than 50% incidence of adverse effects to sensitive species and/or life stages is likely to occur. The ER-L and ER-M are not regulatory cleanup standards. An exceedence indicates a potential risk to the benthic community and helps determine the need for further investigations (e.g., toxicity testing, tissue bioassays, etc.). However, an exceedence of the ER-L/ER-M criteria does not necessarily mandate further investigations if the sediments proximal to the Site have similar contaminant concentration ranges to upgradient sediments. As stated previously, the samples were collected beginning with the downstream location (B-1) and proceeding to the upstream location (B-11). Therefore, the upgradient sediments are most closely represented by the laboratory data for location B-11 (see **Table 4-1**). No PCBs were detected in sediment samples collected at this location.

Based on the *NJDEP Guidance for Sediment Quality Evaluations* (November 1998), the Lowest Effects Levels (LEL) and the Severe Effects Levels (SEL) are to be used as guidelines for individual Arochlors. Arochlor 1254 is the only Arochlor found at the Landfill Sites shown on **Figure 2-3**. The LEL indicates concentrations at which adverse benthic impacts may begin to occur (level tolerated by most benthic organisms). The SEL is a contamination level that indicates severe impacts to the benthic community in most cases studied. Both the LEL and the SEL are derived from freshwater sediment screening criteria; however, they are used in conjunction with the marine/estuarine ER-L and ER-M values for screening purposes. The ER-L and ER-M apply to Total PCBs, whereas the LEL and SEL can be used for screening purposes for individual Arochlors.

In the case of non-polar organic compounds, such as PCBs, it may be necessary to modify the SEL to create a Site-specific SEL (SSEL) based on the Total Organic Carbon (TOC) fraction present in the sample. The TOC fraction is used to determine if the samples were collected in depositional zones, evidenced by a higher percentage of fine-grained particles. Depositional zones are generally the areas of highest potential contamination and are targeted during Site sampling events. To calculate a SSEL, the SEL is multiplied by the TOC fraction. If the TOC of the samples is not measured during sampling, as is the case at the M-12/M-14 Site, a default value of 1% is used. In this instance, each SEL is multiplied by 0.01 to derive the SSEL for comparison purposes. At M-12/M-14, no Arochlors were detected. However, at other Fort Monmouth Landfill Sites, the only Arochlor detected in the sediments was Arochlor 1254. The LEL, SEL and SSEL for Arochlor 1254 are shown below.

Polychlorinated Biphenyl	LEL (mg/kg, dry weight)	SEL (mg/kg organic carbon, dry weight)	SSEL (mg/kg)
Arochlor 1254	0.060	34	0.34

mg/kg=milligrams per kilogram

The USEPA, Region II, and the NJDEP Bureau of Environmental Evaluation and Risk Assessment/Environmental Toxicology and Risk Assessment (BEERA/ETRA) have discontinued the SSEL approach for general screening purposes except in cases of borderline screening exceedances and/or a weight of professional evidence suggesting that the SSEL is appropriate. The SSEL approach is discussed here for completeness, but was not otherwise used to formulate Site-related environmental risk decisions or conclusions.

The results of the PCB laboratory analysis indicated one detection above the laboratory MDL in the duplicate sample of M12M14/9 0-6". This detection is likely to be an anomalous result because PCBs were not detected in M12M14/9 0-6". Additionally, the result appears to be an isolated occurrence because no other upgradient landfill sites (M-3, M-4 and M-5) have presented similar PCB exceedances.

This sample result exceeds both the NJDEP Effects Range – Low (ER-L) and Effects Range – Medium (ER-M) guidance concentrations for Total PCBs (0.023 mg/kg and 0.180 mg/kg, respectively). The ER-L and ER-M represent the concentrations at which adverse benthic effects are found in approximately 10% and 50% of studies, respectively. This sample also exceeds the Arochlor 1254 (the only Arochlor detected at the Site) LEL of 0.060 mg/kg, the concentration at which adverse benthic impacts may begin to occur (the level tolerated by most benthic organisms). The PCB detection did not exceed the SSEL for Arochlor 1254 (0.34 mg/kg). As such, this result, if not anomalous, is unlikely to result in long-term adverse benthic effects in Husky Brook.

Due to the presence of only one potentially anomalous result that did not exceed the SSEL for Arochlor 1254, no potential exists for long-term adverse benthic effects in Husky Brook associated with the M-12/M-14 Landfill Site.

The sample results are summarized in **Table 4-1: PCB Sample Results Summary – M-12/M-14 Landfill Site**. The laboratory data sheets are available in **Appendix D**.

4.2 QA/QC

In order to verify the reliability of the analytical results, Versar reviewed the holding times for each sample and the results of the analysis of two field duplicate samples. All samples were analyzed by the FMETL within the prescribed holding time requirements for each analytical method.

Two field duplicate samples were collected during the Site sampling events to verify the consistency of the entire sampling and analysis procedure. The results for the two duplicate samples were close to those obtained for the original samples. The relative percent difference (RPD) was calculated for each duplicate sample. The RPD measures variability introduced by both the laboratory and field operations. The RPD for the duplicate samples was 175.6%. This RPD exceeds the established limit of 50% for laboratory duplicate samples. However, this is due to low sample concentrations and a correspondingly low MDL used by the laboratory and is not indicative of poor precision because the differences noted may be attributed to analytical sensitivity. Also, the comparison of one very small number with another very small number will result in a high RPD.

5.0 CONCLUSIONS

Based on the results of this sediment quality evaluation, no PCBs were detected above the NJDEP guidance criteria for sediment quality in any sample, and no potential exists for long-term adverse benthic effects in Husky Brook associated with the M-12/M-14 Landfill Site. Therefore, No Further Action is recommended for the M-12/M-14 Landfill Site related to potential PCB impacts to the sediments of Husky Brook.

Re: Sediment Sampling Plan
Sites M-2, M-3, M-4, M-5, M-8, M-12, M-14, M-18 and CW-3A
Fort Monmouth Main Post/Charles Wood
Tinton Falls, Monmouth County

Dear Mr. Fallon:

The NJDEP has reviewed the March 29, 2000 Sediment sampling plan for the nine former landfill sites referenced above and we accept the plan as submitted.

The referenced document, developed with NJDEP using appropriate technical guidance documents and requirements, is specifically designed to determine if PCBs have impacted adjacent surface waters.

There are a few brief comments which we have previously discussed, but I wanted to note here as a reminder for you in this investigation.

- The NJDEP requires PCB method 8082 to be utilized.
- Approved sample preservation methods must be used if volatile compounds are to be investigated or reported on.
- Some discussion regarding the sediment criteria utilized along with a discussion on the application to the sample location and water body must be provided in the final report.
- Sampling must be performed on downgradient samples first.

If you should have any questions or comments, please do not hesitate to contact me at (609) 633-7232 or via E-mail.

Sincerely,

Ian R. Curtis, Case Manager
Bureau of Case Management
ICURTIS@DEP.STATE.NJ.US

Re: Sediment Sampling Plan for Nine Former Landfill Sites
(i.e. M-2, M-3, M-4, M-5, M-8, M-12, M-14, M-18 & CW-3A)
Main Post and Charles Wood Area, Fort Monmouth, New Jersey

Dear Mr. Curtis:

Submitted for your review and approval, please find a copy of the above referenced sampling plan. Said plan should enable the Directorate of Public Works to ascertain whether polychlorinated biphenyls are present within stream sediments bordering the nine referenced landfills. Future site work will be based upon the findings of this sampling initiative.

Should you have any questions or require any additional information regarding this plan, please contact the undersigned at the following telephone number: (732) 532-6223.

Sincerely,

Joseph M. Fallon

Joseph M. Fallon, CHMM

1.0 SAMPLING ACTIVITIES

1.1 OVERVIEW

This report provides details for a proposed sediment sampling plan as prepared by TECOM-Vinnell Services (TVS) on the behalf of the U.S. Army Fort Monmouth, Directorate of Public Works (DPW), Fort Monmouth, New Jersey. The purpose of this sampling initiative is to ascertain whether Polychlorinated Biphenyls (PCBs) are present within stream sediments which border nine former landfill sites (i.e. M-2, M-3, M-4, M-5, M-8, M-12, M-14, M-18 and CW-3A). The streams associated with this investigation include Mill Creek, Lafetra Creek, Parkers Creek, Husky Brook, and an unnamed tributary of Wampum Brook (see attachments 1 & 2). The data generated from this study will be used in conjunction with other previously collected data involving surface soils, subsurface soils, ground water and surface water. As part of the larger, ongoing remedial investigation at these nine landfill sites, PCBs were identified within subsurface soils at landfill sites M-2 and M-8. The Final Site Investigation (SI) Report, Fort Monmouth, New Jersey, Main Post and Charles Wood Areas (December 1995) identifies electronic components as one of the waste types being disposed of within the subject landfills. Said components (i.e. electrical ballasts) typically contained small quantities of insulating oil which may or may not have contained PCBs. Based upon the potential presence of electronic components at the other seven landfill sites, PCBs may also exist within subsurface soils at these locations. As part of previously conducted sampling initiatives, the DPW has been able to document that the PCBs identified at sites M-2 and M-8 have not impacted site ground water or surface water. Furthermore, PCBs have not been identified within site ground water or surface water at the other landfill sites. The overall goal of the proposed sampling plan is to document that the presence of PCBs at sites M-2 and M-8 have not impacted the nearby stream sediments.

This investigation will be conducted by TVS personnel in accordance with the specifications required for collecting sediment samples as determined by the New Jersey Department of Environmental Protection (NJDEP) Field Sampling Procedures Manual (May 1992) and the NJDEP Guidance For Sediment Quality Evaluations (November 1998).

1.2 SITE DESCRIPTION

Mill Creek is located along the northern side of the M-2 landfill (approximate distance 1,400 feet) and along the western side of the M-4 landfill (approximate distance 360 feet) and the M-5 landfill (approximate distance 570 feet). Lafetra Creek runs along the northern side of the M-3 landfill (approximate distance 1,200 feet), joining with Mill Creek to form Parkers Creek. Parkers Creek surrounds the M-8 landfill (approximate distance 1,500 feet) on the western, northern, and eastern sides. It then runs along the western side of the M-18 landfill (approximate distance 700 feet). Husky Brook runs along the northern side of the M-12 landfill, eventually running between the M-12 and M-14 landfills (combined approximate distance 1,700 feet) before flowing into Oceanport Creek. An unnamed tributary of Wampum Brook is located along the northern side of the CW-3A landfill (approximate distance 600 feet). Stream banks along the landfills vary from heavily vegetated with trees and bramble to simply grass. A stream bank restoration project is currently underway at the landfill sites located on the Main Post. The project entails stabilizing the stream banks through a combination of hard (rip-rap) and soft (vegetative plantings) engineering practices. All sites vary in steepness and have various access points. The streams flow constantly even in drought conditions and all but the unnamed tributary of Wampum Brook are tidally influenced. Currents and depth vary with tide.

1.3 HEALTH AND SAFETY

Before sampling activities commence, potential site hazards (physical, chemical and biological) will be evaluated by the TVS Health and Safety Office. A site specific Health and Safety Plan shall be prepared accordingly.

2.0 SITE INVESTIGATION ACTIVITIES

2.1 CONTACTS AND PERSONNEL

The following is a listing of all contacts and personnel involved in the investigation. All analyses are to be performed and reported by U.S. Army Fort Monmouth Environmental Laboratory, NJDEP- Certification # 13461. All sampling will be performed under the direct supervision of a NJDEP trained sample technician according to the methods described in the NJDEP Field Sampling Procedures Manual (1992) and as defined in this sampling plan.

The following parties are participants in this investigation:

- Environmental Protection Specialist: Joseph Fallon, CHMM
  Employer: U.S. Army, Fort Monmouth Phone Number: (732) 532-6223
- Field Technician: Corey McCormack
  Employer: TECOM-Vinnell Services (TVS) Phone Number: (732) 532-0989
- Analytical Laboratory: U.S. Army Fort Monmouth Environmental Laboratory
  Contact Person: Daniel Wright - Phone Number: (732) 532-4359
  Employer: TECOM-Vinnell Services
  NJDEP Certification No.: 13461
- Field Technician Supervisor: Mark Laura
  Employer: TECOM-Vinnell Services (TVS) Phone Number: (732) 532-0989
- Health and Safety Personnel: Bruce Wadlington, Chandra Jennings, and John Wierbowski. Employer: TVS - Phone Number: (732) 532-1706

2.2 SAMPLING PROCEDURES AND PROTOCOL

During the investigation, all samples will be collected with proper attention to quality assurance protocols and in accordance with the guidelines set forth by the New Jersey Department of Environmental Protection (NJDEP) Field Sampling Procedures Manual (May, 1992), the Technical Requirements for Site Remediation (NJAC 7:26E, June, 1993) and the NJDEP Guidance for Sediment Quality Evaluations (November 1998).

2.2.1 SITE ACTIVITES

Site activities shall include recording field conditions and other relevant observations, sampling sediments, plotting sample locations by usc of our Global Positioning Systcm (GPS), decontamination of equipment, and preservation and storage of samples.

2.2.2 SEDIMENT SAMPLING

Sample locations will be determined, sampled, and recorded in the following way:

1. Samples will be taken from clearly discernable depositional areas in and along the streams. In the event that no clear depositional areas can be located, a sample will be taken from the best possible stream bed point at the rate of 1 sample for every 100 feet.
2. Samples will be taken at a depth of 0-6 inches for surface deposits and 6-12 inches for subsurface deposits in each sampling event. Based upon the individual thickness of each depositional area, an 18-24 inch deep sample will also be taken if the desired depth is obtainable.
3. Sampling will commence from downstream, working upstream. Care will be taken to minimize disturbance of sediments and washing of samples as collected.
4. Tide, weather, recent activity, and notable observations will be recorded.
5. A boring log shall be created to note any layers, particle sizes, and defining aspects to each boring.
6. Sampling will be conducted using a hand core sediment sampler.
7. Samples for PCBs analysis will be collected into new, pre-cleaned, 4oz.clear glass jars with Teflon lined caps. All samples will be stored in a cooler at 4 degrees Celsius.
8. After each sampling event, equipment will be decontaminated as stated in section 2.3.
9. Each sample location will be plotted using our GPS.

2.2.3 QA/QC

Quality control samples are required to verify that the sample collection and handling process has not affected the quality of the sediment samples. All field quality control samples will be prepared exactly as regular investigation samples with regard to volume and containers. The following quality control samples will be collected for each batch of samples:

- Field duplicate daily or one every 20 samples; homogenized before splitting.

2.3 EQUIPMENT DECONTAMINATION

Decontamination will be done after every sampling event by the following procedure:

1. Alconox and water wash
2. Water rinse
3. Deionized water rinse
4. Air dry

Landfill Stream Sediment PCB's Sample Event Site Field Summary for M12/M14

Husky Brook runs along the northern side of the M12 landfill, eventually running between M12 and M14 landfills (approximately 1700 feet total) before flowing out into Oceanport Creek.

This stream has had all the lower portions of bank on both landfill sides worked on as part of the stream bank restoration project. Previously the banks were just grass covered here, exposed and eroding away into the brook. It currently is covered with large rock and rip-rap. There is little debris in the stream itself in the lower portion.

Further upstream, it is a mixed bank of tree, bramble, and smaller vegetation. There are man made materials and garbage on the banks and in the streambed here. Most materials are old poles, and rail ties. Some lighter restoration work has been done.

Flow is constant, and depth varies with tide. Even at low tide there are pools 3-4 feet deep. Most occur in the lower portion of the brook. The weather at time of sampling was cold, and sunny. There was a rain/snow event a day prior to the sampling. Tide was low.

Depositional areas are scattered here as well. Sampling targeted these areas. When none were available, 1 sample per 100 feet was taken.

Date Stamp (For Department use only)

SECTION A. CASE INFORMATION

Case Name: Landfill M-14 (FTMM-14) Fort Monmouth, New Jersey

Case ID/Case Number: _____ Preferred ID (PI Number): _____

CEA Component Information

1. **Contaminant(s):** This CEA/WRA applies only to the contaminants above the applicable numeric values established by Ground Water Quality Standards (GWQS), N.J.A.C. 7:9C, listed in the table below. List below the maximum value for all contaminants included in Exhibit A using any well or sampling point used to establish the CEA.

Contaminant	Concentration [1]	GWQS [2]	SWQS [3]	GWSL [4]
Lead	9.32	5	N/A	N/A

Notes: [1] Maximum concentration in Micrograms Per Liter
[2] New Jersey Ground Water Quality Standards, N.J.A.C. 7:9C
[3] Surface Water Quality Standards, N.J.A.C. 7:9B - Applicable only where contaminants in the CEA may discharge to a surface water body.
[4] Ground Water Screening Levels from most current NJDEP Vapor Intrusion Guidance

☐ If attaching an Addendum to list additional contaminants and associated information.

☒ **Exhibit A: Monitor Well/Sampling Point Data** – Per N.J.A.C 7:26E-8.3(b) submit a copy of a table that includes the most recent 24 months of ground water sampling.

2. **CEA Boundaries:**
Lot(s) and Block(s) included in the areal extent of the Classification Exception Area:

Year of tax map used: 2005

Block(s)	Lot(s)	Check if off-site
Oceanport 110	1	☐
		☐
		☐
		☐
		☐

Block(s)	Lot(s)	Check if off-site
		☐
		☐

		☐
		☐

☐ If attaching an Addendum to list additional Blocks/Lots and associated information.

☒ **Exhibit B: Site Location Maps** – USGS Quadrangle Map and Tax Lot and Block Map (N.J.A.C. 7:26E-8.3(b)3i and ii)

☒ **Exhibit C: Site Map(s) and Cross Section** – Including actual/predicted contaminant isopleths, ground water flow direction, CEA boundary, monitor well/sampling point/boring locations/IDs, area(s) of concern. N.J.A.C 7:26E-8.3(b)3iii through v.

Insert NAICS responsible for area(s) of concern, if known: _____

Narrative description of proposed CEA:

Due to lead exceedances, the horizontal extent of the CEA is defined by the Site monitoring well network. The vertical extent of the CEA includes the shallow part of the aquifer beneath the Site and it extends from the water table to approximately 18 feet bgs, which represents the total depth of the contaminated wells at the Site.

Name of the affected Geologic Formation/Unit: Navesink Hornerstown

Direction of ground water flow: S-SE

Ground Water Classification: II-A

Vertical Depth of CEA (ft bgs and msl)	Horizontal Extent of CEA (acres or square ft)
~18 ft bgs (~2 ft msl)	59,580 square feet (2.10 acres)

☒ **Exhibit D: Vertical Contaminant Data** – A table, for the most recent 24 months of data, for each sampling point used to establish the CEA, or the subset of wells indicated in N.J.A.C 7:26E-8.3(b)3iii, iv and v, that includes the following:

Depth (in feet bgs and msl elevation) to:

Water Table	Approximate Bottom of Plume[5]	Top of Plume[6]	Thickness of Clean Water Lens[6]

Notes: [5] Approximate maximum depth of contamination based on data included in Remedial Investigation Report (RIR);
[6] Required only if plume is known to be below the water table based on vertical profiling or monitor well data in RIR.

Exhibit E: Fate and Transport Description and Model Documentation

☐ Historic Fill exemption

☒ All information required pursuant to N.J.A.C. 7:26E-8.3(b)2 and applicable guidance is included.

3. Projected Term of CEA: Based on modeling/calculations in Exhibit E

Proposed Duration in Years: Indeterminate

SECTION B. CURRENT AND PROJECTED GROUND WATER USE DOCUMENTATION

☒ **Exhibit F: Well Search Results** – Include most recent well search per N.J.A.C. 7:26E-1.17.

Check each item where, pursuant to N.J.A.C. 7:26E-8.3(b)4, written documentation was obtained regarding future ground water use for a 25-year planning horizon based on:

☒ Municipal master plans

☒ Zoning plans

☒ Local water purveyor plans and planning data pertaining to the existence of water lines and proposed future installation of water lines

☒ Local planning officials

☒ County and local boards of health

☒ Local and/or county ordinances restricting installation of potable wells

SECTION C. WELL RESTRICTION INFORMATION

For Class II-A ground water and pursuant to the GWQS at N.J.A.C. 7:9C-1.6(d), where ground water quality data indicate contaminants exceed the values listed in the Primary Drinking Water Regulations, the Department shall restrict, or require the restriction of, potable ground water uses within any CEA. Therefore, the CEA established for this site is also a Well Restriction Area, the extent of which coincides with the boundaries of the CEA.
Well Restrictions set within the boundaries of the CEA:

☒ Double Case Wells

☒ Sample Potable Wells

☒ Evaluate Production Wells

☐ Other

SECTION D. PUBLIC NOTIFICATION REQUIREMENTS

Notify Department that letters were sent per N.J.A.C. 7:26E-8.3(b)5 (check all applicable categories):

- ☒ Municipal and county clerk(s)
- ☒ Local, county or regional health department(s)
- ☒ Designated County Environmental Health Act agency (if applicable)
- ☒ County Planning Board
- ☐ Pinelands Commission (if applicable)
- ☐ Owners of real property overlying CEA foot print

☐ **Exhibit G: List of Names and Addresses** – Include all persons notified pursuant to N.J.A.C. 7:26E-8.3(b) based on the proposed CEA extent.

EXHIBIT A

1.0 INTRODUCTION

This report discusses current ground water conditions and presents a ground water Classification Exception Area (CEA) for the Fort Monmouth M-14 Landfill, known as the FTMM-14 area (hereinafter referred to as the Site).

The work recently completed consisted of reviewing the most recent ground water sample collection (4th Quarter 2009 through 3rd Quarter 2010) to select the constituents of potential concern (COPCs) at the Site [the constituents with concentrations greater than the New Jersey Department of Environmental Protection (NJDEP) Ground Water Quality Standards (GWQS)].

Brinkerhoff Environmental Services, Inc. (Brinkerhoff) completed this work in accordance with current NJDEP guidelines, specifically the procedures described in the *Final Guidance on Designation of CEAs* and the *Technical Requirements for Site Remediation* (*Technical Requirements*), New Jersey Administrative Code. (N.J.A.C) 7:26E-8.4, last amended on November 4, 2009.

The following sections of this report provide the information required to define the CEA for the Site. Included are the following:

- A description of subsurface stratigraphic and hydrogeologic conditions on-site;
- A description of the ground water quality at the Site;
- A list of COPCs at the Site known to be present at concentrations greater than the NJDEP GWQS;
- A determination of the horizontal and vertical extent of the CEA;
- A determination of the duration of the CEA;
- A written and mapped description of the CEA, including electronic and paper copies of the map of the CEA compatible with the NJDEP Geographic Information Systems (GIS North American Datum [NAD] 83);
- An evaluation of the area encompassed by the CEA to determine if the area is a ground water use area as defined by NJDEP; and
- Notification to the appropriate agencies of the intent to establish the CEA.

2.0 BACKGROUND

2.1 Site Setting and History

The M-14 Landfill is one of the Main Post areas of concern (AOCs) at the Fort Monmouth United States (U.S.) Army installation located in the Borough of Oceanport, Monmouth County, New Jersey. Landfill operations at the site began circa 1960. The types of materials reportedly disposed at the landfill have been reported to include construction debris, scrap metal, asbestos-containing materials, vegetative waste, unwashed containers which previously held hazardous materials/wastes, outdated photographic chemicals, small quantities of outdated drugs, sludge from the sewage treatment plant, soot and boiler scale, incinerator ash, oil spill debris, oil filters, batteries, fluorescent tubes, and electronic components.

2.2 Monitoring Well/Sampling Point Data

The Fort Monmouth DPW sampled ground water monitoring wells at the M-14 Landfill from the 4th Quarter of 2008 through the 3rd Quarter of 2010. All ground water samples were analyzed for TAL Metals.

Six metals (antimony, arsenic, beryllium, cadmium, lead, and thallium) were detected in ground water at the Site during the last eight sampling events at concentrations exceeding NJDEP GWQS. These metals and their concentrations are presented on Table A-1 located within this exhibit.

Metals are known to migrate slowly and not degrade. Metals in ground water throughout Fort Monmouth were evaluated using statistical analyses and published literature information (Brinkerhoff, 2011 *Background Metals Evaluation*). It was concluded that the metals in ground water are likely a combination of a natural dissolved component along with input from sample turbidity. Due to the interference from sample turbidity, exceedances of the GWQS by actual dissolved-phase metals are not certain.

The presence of arsenic, antimony, beryllium, cadmium, and thallium at the Site is attributed to naturally occurring background conditions. Therefore, they are not considered COPCs, and are not included in the CEA application.

Due to its common industrial use, the source of lead is less certain, and therefore remains a COPC and is included in this CEA. Based on the findings of Brinkerhoff's *Background Metals Evaluation*, modeling of the metals is not practical, and the CEA time-frame is therefore indeterminate. (Refer to the Background Metals Evaluation prepared by Brinkerhoff in 2011 for more information.)

2.3 Regional Geology and Hydrogeology

Fort Monmouth is located in the central-eastern portion of New Jersey in Monmouth County, approximately 45 miles south of New York City, 70 miles northeast of Philadelphia, and 40 miles north of Trenton. The Atlantic Ocean is approximately 3 miles to the east. Fort Monmouth falls within the boroughs of Eatontown, Oceanport, and Tinton Falls. The areas surrounding Fort Monmouth are characterized by a mixture of residential, commercial, and light industrial uses. Fort Monmouth occupies approximately 1,126 acres and is currently comprised of two operational areas: the Main Post and the Charles Wood Area. The two areas are located about 2 miles from one another.

Previous geologic investigations prepared for the Site have described the underlying shallow unconsolidated deposits below ground surface (bgs) as "predominantly derived from deltaic, shallow marine, and continental shelf environments", consisting of "clay, silt, sand, and gravel" (DPW Environmental Office 1997). The Soil Survey of Monmouth County classified most of the soil on the Main Post as urban land (developed land with disturbed soils) and labeled the soil as Udorthent soils, which are soils altered by excavating or filling. The small portion of the Main Post, which is otherwise classified, includes a mixture of soil types (loam, clay, sandy loam, etc.) and has low to moderate permeability and is poorly-to-well-drained. The Site is underlain by the Navesink formation and the Hornerstown sand, a class II-A aquifer.

EXHIBIT C

1.0 CLASSIFICATION EXCEPTION AREA (CEA) BASIS

The NJDEP requires that the CEA application specify the constituents that will require an exception to the NJDEP's GWQS. These are constituents necessitating the institution of a CEA because they are either currently detected or are anticipated to be detected in the future at concentrations exceeding applicable NJDEP GWQS.

As indicated in Exhibit A, the presence of arsenic, antimony, beryllium, cadmium, and thallium at the Site is attributed to naturally occurring background conditions. They are therefore not considered COPCs, and are not included in the CEA application.

Due to its common industrial use, the source of lead is less certain, and therefore it remains a COPC and is included in this CEA.

2.0 EXTENT OF THE CLASSIFICATION EXCEPTION AREA (CEA)

The horizontal extent of the CEA encompasses the area illustrated on Figure C – 1.

The horizontal extent of the CEA is defined by the Site monitoring well network, as exceedances of the GWQS for lead were identified for multiple wells during recent sampling events.

The CEA at the M-14 Landfill is based on the area outlined by ground water monitoring wells M14MW19, M14MW20, M14MW22, and M14MW24, encompassing an area of approximately 59,580 square feet or 2.1 acres.

The vertical extent of the Site CEA includes the shallow part of the aquifer beneath the Site and it extends from the water table to approximately 18 feet bgs, which represents the total depth of the contaminated wells at the Site.

Exhibit D

Vertical Contaminant Data

EXHIBIT D

1.0 VERTICAL CONTAMINANT DATA

Pursuant to N.J.A.C 7:26E-8.3(b)3 iii, iv, and v, Brinkerhoff Environmental Services, Inc. has provided vertical contaminant data for the Site in Table D-1. The vertical extent of the Site CEA includes the shallow part of the aquifer beneath the Site, and it extends from the water table to approximately 18 feet bgs, which represents the total depth of the contaminated wells at the Site.

There is no known clean water lens as contamination is believed to be at water table elevation.

Exhibit E

Fate and Transport Description and Model Documentation

EXHIBIT E

1.0 Duration of Classification Exception Area (CEA)

Metals are known to migrate slowly and not degrade. Metals in ground water throughout Fort Monmouth were evaluated using statistical analyses and published literature information (Brinkerhoff, 2011 Background Metals Evaluation). It was concluded that the metals in ground water are likely a combination of a natural, dissolved component along with input from sample turbidity. Due to the interference from sample turbidity, exceedances of the GWQS by actual dissolved-phase metals are not certain, and modeling of the fate and transport is not practical. The CEA time-frame is therefore indeterminate.

As indicated in Exhibit A, The presence of arsenic, antimony, beryllium, cadmium, and thallium at the Site is attributed to naturally-occurring background conditions. Therefore, they are not considered COPCs, and are not included in the CEA application.

Due to common industrial use, the source of lead is less certain, and therefore remains a COPC and is included in this CEA.

Future sampling should aim to reduce the input from sample turbidity, and thus better represent the actual concentrations of dissolved-phase lead. Upon completion of each sampling event, the data should be compared to the GWQS. Lead concentrations laboratory-determined to be in compliance with the GWQS should be removed from further consideration.

2.0 Written and Mapped Description of the CEA

N.J.A.C. 7:26E-6.2(a)17 requires submittal of a map of the CEA compatible with the NJDEP's Geographic Information Systems both as a paper hard copy and electronically by means of a computer disk. Exhibit C, Figure C-1, with supporting written documentation provided above, represents a paper copy, and an electronic copy of the map of the CEA, as a shape file, is provided along with Metadata as Attachment I to this submittal.

EXECUTIVE SUMMARY

This Remedial Investigation Report Addendum (RIRA) documents the remedial activities conducted by the Army to investigate soil, ground water, surface water, and sediment conditions at the M-14 Landfill, located in the Main Post Area of Fort Monmouth, New Jersey. This RIRA details remedial investigation activities conducted from the 2nd Quarter 2001 - 3rd Quarter 2010.

The M-14 Landfill is approximately 6.9 acres and is bordered by Murphy Drive to the east, Husky Brook and the M-12 Landfill to the south, and residential properties to the north and west. The M-14 Landfill was in use from 1965-1966 for disposal of building demolition debris.

In 1993, a background investigation was conducted by Roy F. Weston, Inc. (Weston) for 45 sites identified by Fort Monmouth and the New Jersey Department of Environmental Protection (NJDEP). Weston's findings were detailed in a report entitled: *Investigation of Suspected Hazardous Waste Sites at Fort Monmouth, New Jersey* (1993). In the report, Weston recommended additional remedial investigation for the M-14 Landfill. In 1995, Weston conducted additional site investigation activities at 22 sites, including the M-14 Landfill – detailing their findings in a *Site Investigation Report* (December 1995). Initial field investigation activities included near-surface soil sampling, sediment sampling, surface water sampling, installation of monitoring wells, and ground water sampling. Based on the findings of Weston's 1995 SIR, the Army implemented a long-term ground water monitoring program. Seven ground water monitoring wells (M-14MW18, M-14MW19, M-14MW20, M-14MW21, M-14MW22, M-14MW23, and M-14MW24) currently comprise the quarterly ground water monitoring program.

Versar, Incorporated (Versar) prepared a *Remedial Investigation Report and Sediment Quality Evaluation for the M-14 Landfill* (October 2003) and a *Remedial Investigation Report for Near-Surface Soils* (March 2004), which summarized sampling activities conducted by the Army to characterize Husky Brook sediments and near-surface landfill soil, respectively. In August 2005, Versar prepared a *Remedial Investigation Report* (RIR), detailing remedial investigation activities conducted at the M-14 Landfill from 2nd Quarter 1997 – 1st Quarter 2001.

From December 28, 1998 to May 13, 2010, the Army characterized near-surface landfill soil via advancement of 203 soil borings across the M-14 Landfill. In December 2008, the Army conducted landfill boundary delineation activities to refine the dimensions of the M-14 Landfill. The landfill boundary delineation study involved advancement of test pits and soil borings. Near-surface soil concentrations of arsenic, lead, and six semi-volatile organic compounds [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene] exceeded NJDEP Non-Residential Direct Contact Soil Remediation Standards (NRDCSRS). Arsenic and lead are not considered M-14 Landfill contaminants of concern (COCs) because they are naturally-occurring within Fort Monmouth soils.

During the current reporting period (2nd Quarter 2001 – 3rd Quarter 2010), ground water sampling was conducted quarterly. For the last eight ground water sampling quarters (4th Quarter 2008 – 3rd Quarter 2010), only metals (antimony, arsenic, beryllium, cadmium, lead, nickel, and thallium) exceeded NJDEP Ground Water Quality Standards (GWQS). Metals are not considered COCs at the M-14 Landfill because they are naturally-occurring within Fort Monmouth soils. Metal detections in general, and lead specifically, are the direct result of acid leaching of suspended solids in ground water samples. In addition, due to the extremely slow migration rates of metals in ground water, they pose little potential for migration. Since no COCs exceed NJDEP GWQS in M-14 Landfill ground water monitoring wells, a Classification Exception Area is not proposed.

During the current reporting period, surface water samples collected at the nearest upstream sampling point (SS-19) from the M-14 Landfill exceeded NJDEP SWQS for arsenic, bromodichloromethane, and lead. Surface water samples collected at the nearest downstream sampling point (SS-09) from the M-14 Landfill exceeded NJDEP SWQS for arsenic and lead. Metals are not considered COCs in Husky Brook because they are naturally-occurring within Fort Monmouth sediments. The detection of metals in surface water is due to a combination of a natural, dissolved component along with input from sample turbidity. Bromodichloromethane was detected during the June 2010 stream sampling event at stream sampling point SS-19. This is considered and isolated detection and is the first time bromodichloromethane has been detected at SS-09 since surface water sampling began at Husky Brook in 3rd Quarter 1996. Thus, bromodichloromethane is not considered a COC at the M-14 Landfill.

Future plans include collection of quarterly ground water and surface water samples until closure of Fort Monmouth in September 2011. At that time, future sampling will be evaluated and discussed with NJDEP. The Army plans to prepare a Remedial Action Selection Report (RASR)/Feasibility Study (FS) as the next report submittal, which will include a final closure plan for the M-14 Landfill.

1.0 INTRODUCTION

This Remedial Investigation Report Addendum (RIRA) documents the remedial investigation activities conducted by the Army from the 2nd Quarter 2001 – 3rd Quarter 2010 to investigate soil, ground water, surface water, and sediment conditions at the M-14 Landfill.

1.1 Objectives

The objective of this RIRA is to document the site investigation activities conducted at the M-14 Landfill during the current reporting period of the 2nd Quarter 2001 – 3rd Quarter 2010. Natural attenuation with a long-term ground water monitoring program was implemented by the Army as a remedial action (RA) for the M-14 Landfill, based on recommendations in Weston's SIR (December 1995) and subsequent remedial investigation reports prepared by Versar, including: *RIR and Sediment Quality Evaluation for the M-14 Landfill* (October 2003), *RIR for Near-Surface Soils* (March 2004), and RIR (August 2005). Copies of the above-referenced reports are provided in Appendix A. All remedial activities were conducted in accordance with the NJDEP's *Technical Requirements for Site Remediation* (*Technical Requirements*), New Jersey Administrative Code (N.J.A.C.) 7:26E *et seq*.

The RIR and subsequent preparation of this RIRA encompassed the following:

- Conducting quarterly ground water and surface water sampling and documenting the results to evaluate the effectiveness of the RA.
- Comparing the results of ground water and surface water sampling to the appropriate NJDEP GWQS and SWQS.
- Characterizing near-surface landfill soil and Husky Brook sediments.
- Identifying and discussing recommendations for the RA.
- Documenting remedial activities as required by the *Technical Requirements*.

1.2 Report Organization

Section 2.0 discusses the site history and background information for the M-14 Landfill. Section 3.0 summarizes the remedial activities conducted. Section 4.0 discusses ground water and surface water monitoring and sampling activities. Section 5.0 presents the laboratory analytical results of soil, ground water, and surface water sampling. Sections 6.0 and 7.0 discuss the Background Metals Evaluation and receptor evaluation, respectively. Section 8.0 discusses the effectiveness of the RA and provides recommendations for the M-14 Landfill. Section 9.0 is the reference section.

2.0 SITE BACKGROUND

The following sections describe the site background of the M-14 Landfill. Included is a description of the site location, site history, background investigations, and previous technical reports.

2.1 Site Location and Description

Fort Monmouth is located in the central-eastern portion of New Jersey in Monmouth County (Figure 2-1). The M-14 Landfill is approximately 6.9 acres and is bordered by Murphy Drive to the east, Husky Brook and the M-12 Landfill to the south, and residential properties to the north and west (Figure 2-2). The M-14 Landfill was in use from 1965-1966 for disposal of building demolition debris. Since 1966, there has been growth and stabilization of vegetation (grass, trees, and bushes) along the surface and boundaries of the landfill. General utilities servicing M-14 Landfill are depicted on Figure 2-3. Wetlands present on the Main Post are depicted on Figure 2-4.

2.2 Environmental Setting

This section summarizes the description of the geological and hydrogeological setting of the area surrounding Fort Monmouth and the Main Post area as presented in Versar, Inc.'s August 2005 RIR (Appendix A).

2.2.1 Geology

Monmouth County lies within the New Jersey Section of the Atlantic Coastal Plain physiographic province. The M-14 Landfill is located in the Outer Coastal Plain sub-province, or the Outer Lowlands.

In general, New Jersey Coastal Plain formations consist of a seaward-dipping wedge of unconsolidated deposits of clay, silt, sand, and gravel. These formations typically strike northeast-southwest with a dip ranging from 10 to 60 feet per mile and were deposited on Precambrian and lower Paleozoic rocks. These sediments, predominantly derived from deltaic, shallow marine, and continental shelf environments, date from Cretaceous through the Quaternary periods. The mineralogy ranges from quartz to glauconite.

As presented in the Site Investigation Report - Main Post and Charles Wood Areas, Fort Monmouth, New Jersey, prepared by Weston (Weston 1995), several natural and anthropogenic factors contribute to the wide range in concentrations of metals found in soils, which further impact the concentration of metals in ground water. Soils derived from the glauconitic sands contain abundant aluminum, calcium, potassium, iron, magnesium, and manganese (among others), which are likely to be present at elevated concentrations in the ground water, particularly when sediments are entrained in the collected ground water samples.

2.2.2 Hydrogeology

The water table aquifer on the Main Post is identified as part of the "Navesink-Hornerstown Confining Units," or minor aquifers. The minor aquifers include the Navesink formation, Red Bank Sand, Tinton Sand, Hornerstown Sand, Vincentown Formation, Manasquan Formation, Shark River Formation, Piney Point Formation and the basal clay of the Kirkwood Formation. These geologic formations comprise a "Composite Confining Bed" for the Wenonah Mount Laurel Aquifer (Zapecza, 1984).

Wells installed in the Red Bank and Tinton Sands produce approximately 2-25 gallons per minute (gpm) (Jablonski, 1968). Groundwater is typically encountered at the Main Post and in the surrounding areas at shallow depths below ground surface (2-9 feet bgs). Water in the surficial aquifer generally flows east towards the Atlantic Ocean.

Additionally, Brinkerhoff prepared a *MODFLOW Ground Water Modeling Report*, dated June 10, 2010, which is included as Appendix B. In this report, Brinkerhoff developed and refined site-wide ground water models for both the Main Post and the Charles Wood areas of Fort Monmouth (Brinkerhoff 2010).

2.3 Site History and Background Investigations

In 1993, the Army contracted Weston to conduct a background investigation for 45 sites identified by Fort Monmouth and the NJDEP. Weston's findings were detailed in a report entitled: *Investigation of Suspected Hazardous Waste Sites at Fort Monmouth, New Jersey* (1993). In the report, Weston recommended that additional remedial investigation be conducted for the M-14 Landfill. In 1995, Weston conducted additional site investigation activities at 22 sites, including the M-14 Landfill – detailing their findings in a *Site Investigation Report* (December 1995). Initial field investigation activities at the M-14 Landfill included near surface soil sampling, sediment sampling, surface water sampling, installation of monitoring wells, and ground water sampling.

Based on the findings of the Weston's 1995 SIR, the Army implemented of a long-term ground water monitoring program at the M-14 Landfill. Seven ground water monitoring wells (M-14MW18, M-14MW19, M-14MW20, M-14MW21, M-14MW22, M-14MW23, and M-14MW24) currently comprise the quarterly ground water monitoring program.

Versar Incorporated (Versar) prepared a *Remedial Investigation Report and Sediment Quality Evaluation for the M-14 Landfill* (October 2003) and a *Remedial Investigation Report for Near-Surface Soils* (March 2004), which summarized sampling activities conducted by the Army to characterize Husky Brook sediments and near-surface landfill soil, respectively. In August 2005, Versar prepared a *Remedial Investigation Report* (RIR), detailing remedial investigation activities conducted at the M-14 Landfill from 2nd Quarter 1997 – 1st Quarter 2001.

Copies of the above-referenced reports are provided in Appendix A. The following sections summarize previous remedial investigation activities conducted at the M-14 Landfill.

2.3.1 October 2003 Sediment Quality Evaluation

Studies conducted at other Main Post landfills (e.g. M-2 Landfill and M-8 Landfill) indicated that disposal of PCB-containing materials (e.g., electrical ballasts) occurred. PCBs were detected in soil and/or ground water samples collected at both the M-2 and M-8 Landfills. Based on these observations, in the second quarter of 2000, the Army conducted a sediment sampling investigation to evaluate potential impacts to stream sediments in creeks and/or brooks adjacent to Main Post and Charles Wood Area landfills.

On April 10, 2000, to determine potential PCB-related impacts to sediments in Husky Brook, the Army collected 25 surface and near-surface sediment samples from Husky Brook. The samples were collected along the 1,700-foot portion of Husky Brook that bisects the M-12 and M-14 Landfills. Sample depths ranged from surface (0-6 inches) to near-surface (6-12 inches and 18-24 inches). All 25 sediment samples were analyzed for PCBs and compared to sediment sampling guidance concentrations as defined in the NJDEP's *Guidance for Sediment Quality Evaluations* (NJDEP 1998).

With the exception of one anomalous duplicate sample detection of the PCB Arcolor 1254, no PCBs were detected in any of the 25 sediment samples collected from Husky Brook. Based on NJDEP's guidance criteria, PCBs are not impacting sediments in Husky Brook. In addition, no potential exists for long-term, adverse, benthic effects in Husky Brook associated with the M-12 and M-14 Landfills. A No Further Action (NFA) determination for Husky Brook sediments was recommended for the M-12/M-14 Landfills.

Additional details regarding the October 2003 sediment quality evaluation is provided in Versar's *Remedial Investigation Report and Sediment Quality Evaluation for the M-14 Landfill* (Appendix A).

2.3.2 March 2004 Near-Surface Soil Evaluation

To evaluate if the existing soil cover at the M-14 Landfill complies with the Solid Waste Disposal Act of 1965, the Army characterized near-surface landfill soils via installation and sampling of 119 soil borings. From December 1998-January 1999, the Army advanced soil borings and collected soil samples using a 2-inch Geoprobe® Macrocore sampler to a maximum depth of two feet below ground surface (bgs). All sampling activities were conducted in accordance with *Fort Monmouth Standard Sampling Operating Procedures* (DPW 1997) and the NJDEP *Field Sampling and Procedures Manual*. A total of 238 soil samples were collected from the 119 borings and analyzed for volatile organic compounds (VOCs), semi-volatile organic compounds (SVOCs), pesticides, poly-chlorinated biphenyls (PCBs) and total analyte list (TAL) metals. The locations of the borings were established in a grid-like pattern within the

previously designated boundaries of the M-14 Landfill. The *Remedial Investigation Report for Near-Surface Soils* (Versar, March 2004) provides a detailed explanation of the soil sampling activities conducted at the M-14 Landfill (Appendix A).

SVOCs, pesticides, and metals were detected in surface soil samples at concentrations exceeding the NJDEP's Residential Direct Contact Soil Cleanup Criteria (RDCSCC). VOCs and PCBs were detected at concentrations in compliance with the NJDEP's Residential Direct Contact Soil Cleanup Criteria (RDCSCC).

However, given the inactive and undisturbed state of the landfill, the lack of groundwater use at or hydraulically downgradient of the M-14 Landfill, and low COC concentrations in shallow surface soils, No Further Action is recommended for near-surface soils at the M-14 Landfill.

To address near-surface soil samples that do not meet applicable NJDEP soil remediation standards at the M-14 Landfill, the Army proposes to implement landfill capping as an engineering control. A cap that allows for proper drainage and facilitates growth of vegetation is recommended to be implemented. Should areas of significant surface contamination be encountered during the landfill capping activities, then "hot spot" removals shall be undertaken as outlined in the November 17, 2010 NJDEP Regulatory Requirements. This proposed capping action is an appropriate and prudent measure that will provide an ample physical barrier to direct contact by persons and wildlife that may traverse the area and undertake reasonably expected activities. The Army plans to prepare a formal Landfill Closure Plan with the above-referenced recommendations for submittal to NJDEP for review and approval.

2.3.3 November 2004 Reduction of Ground Water Analysis

In November 2004, based on results of long-term ground water monitoring data, the Army requested a reduction in ground water analysis for samples collected from M-14 Landfill monitoring wells. No SVOCs, pesticides, and PCBs were detected at concentrations exceeding NJDEP GWQS in any M-14 Landfill monitoring well since 2001. On November 16, 2004, in an email correspondence to the Army, the NJDEP approved the reduction of ground water sample analysis to VOCs and TAL metals only (Appendix A).

2.3.4 August 2005 Remedial Investigation Report

Following Weston's December 1995 SIR, the Army continued quarterly ground water sampling at the M-14 Landfill, as detailed in Versar's August 2005 RIR (Appendix A).

Sixteen rounds of ground water samples were collected from June 1997 - January 2001 and analyzed for VOCs, SVOCs, pesticides, PCBs, and TAL metals. Ground water samples collected from two additional rounds of sampling using low-flow methodology were analyzed for TAL metals. Ground water concentrations of SVOCs, pesticides, or PCBs were laboratory-determined to be in compliance with NJDEP GWQS. One VOC, *tert*-butyl-alcohol (TBA), was

detected at concentrations exceeding NJDEP GWQS in one well (M-14MW20) during one round of ground water sampling (1st Quarter 1998). TBA was detected at a concentration of 101.37 µg/L, exceeding the NJDEP GWQS of 100 µg/L. This TBA detection was considered an isolated event as TBA concentrations for all subsequent ground water sampling events at M-14MW20 have been ND. Twelve metals were detected in ground water samples collected from M-14 Landfill monitoring wells at concentrations exceeding NJDEP GWQS.

Based on the results of ground water sampling conducted from June 1997 - January 2001, Versar concluded that no COCs exist in ground water at the M-14 Landfill. NFA was recommended for ground water.

2.3.5 July 2007 NJDEP Correspondence Letter

On July 25, 2007, the NJDEP sent the Army a correspondence letter (Appendix A), which commented on the following M-14 Landfill reports prepared by Versar:

- August 12, 2005 *RIR for M-14 Landfill*
- March 17, 2004 *RIR for Near Surface Soils, M-14 Landfill*
- October 15, 2003 *RIR and Sediment Quality Evaluation, M-12/M-14 Landfill*

The NJDEP's July 25, 2007 comments are summarized in the following sections.

M-12 and M-14 Landfills Recognized as One Site

NJDEP considers the M-12 and M-14 landfills one site, separated by Husky Brook, which bisects the two landfills. NJDEP further stated that the Army has recognized these sites as one site with regards to the sediment quality evaluation and, to a lesser extent, the surface water evaluation. Additionally, NJDEP stated that the soil and ground water sampling results from both landfills are similar, and the respective RIRs have concluded that shallow ground water beneath both landfills flows towards Husky Brook.

Work Plan Submittal

The NJDEP stated that the Army should submit a comprehensive investigation work plan for the NJDEP's review and approval prior to initiating any of the additional sampling requested in the July 25, 2007 NJDEP correspondence letter. A Work Plan was recommended to ensure that the NJDEP and the Army are in agreement on all details prior to commencement of sampling.

Landfill Boundary Delineation

Based on a review of aerial photographs, NJDEP identified potential disposal areas outside the known boundaries of the M-12 and M-14 Landfills. As such, NJDEP requested that the Army

review and revisit the delineation of all landfill areas at Fort Monmouth, including the M-12 and M-14 Landfills. NJDEP further stated that conducting test pits to verify geophysical results of landfill boundaries would be good practice, and verifying landfill boundaries prior to closing and transfer of Fort Monmouth would be in the Army's best interest.

Surface Soils

According to NJDEP, results of surface soil sampling indicated soil in the 0 to 12-inch interval contains SVOCs and metals at concentrations exceeding NJDEP RDCSCC throughout the M-12 Landfill and in two distinct areas of the M-14 Landfill. Therefore, these surface soils have the potential for direct contact, and a remedial action would be required to minimize or eliminate that potential. Depending on the location and extent of the soil contamination exceeding the RDCSCC, targeted soil excavations may be feasible. At a minimum, engineering controls such as additional soil cover, fencing, and warning signs would be required, in conjunction with a deed notice.

NJDEP further stated that in Versar's March 17, 2004 *RIR for Near-Surface Soils*, compliance averaging of soil sample results was done incorrectly in several cases. Also, averaging was applied to arsenic and several polyaromatic hydrocarbons (PAHs), which the NJDEP does not allow because the health-based Soil Cleanup Criteria (SCC) is less than the RDCSCC.

Surface Water and Sediments

NJDEP required a Baseline Ecological Evaluation (BEE) to determine whether receptors, especially within Husky Brook, have been impacted by the M-12 and M-14 Landfills.

NJDEP recommended collection and analysis of sediment samples for TCL+30 and TAL metals. Sampling locations would include one upstream, one downstream, and two locations along the landfills - at least one on each side of the tributary that splits the M-12 Landfill, and one from the tributary that bisects the M-12 Landfill.

NJDEP noted that surface water sample location SS-12, which is in Husky Brook Pond and was used as an upstream sampling point, should be used in the future as an upstream sampling point for both the M-12 and M-14 Landfills.

NJDEP also recommended, based on the presence of measurable VOCs in surface water samples, additional surface water samples should be collected along Husky Brook in conjunction with the recommended sediment sampling. The NJDEP recommended using passive diffusion bags (PDBs) to collect surface water samples for VOC analysis. The PDBs were recommended to be deployed in the sediments to monitor shallow ground water discharging to Husky Brook. In addition, NJDEP requested that the Army evaluate any Army-owned properties upstream of the M-12 and M-14 Landfills that could be the source of the VOC concentrations detected in surface water samples collected from Husky Brook.

Ground Water

Based on the following concerns and deficiencies, NJDEP stated that a NFA could not be issued for ground water:

- Upgradient monitoring wells must be installed and sampled at each landfill to provide data for remedial decision making. Samples from the upgradient wells should be analyzed for TAL metals only.

- An additional round of ground water samples must be collected from all M-12 and M-14 Landfill monitoring wells to provide data for remedial decision making because the existing wells at both landfills may not have been sampled since 2001.

- Approximately four wells, including an upgradient well, should be installed in the western portion of the M-14 Landfill. Ground water samples collected from these wells should be analyzed for TCL+30 and TAL metals.

- Paper copies of all sampling documentation (e.g. ground water field parameters and low-flow sampling sheets) must be submitted with summary tables in future reports.

2.3.6 August 2008 Landfill Delineation Project

On August 1, 2008, to confirm the boundaries of nine solid waste landfills at Fort Monmouth, including the M-14 Landfill, the Army submitted a proposal to the NJDEP to conduct a landfill delineation study involving advancement of test pits and soil borings. The NJDEP reviewed and approved the Army's proposed study in a letter dated August 19, 2008 (NJDEP 2008) (Appendix A).

Details of the M-14 Landfill delineation project are included in Section 3.1 of this RIRA.

2.3.7 February 2009 Regulatory Approach to Fort Monmouth Landfills

In a February 24, 2009 correspondence from NJDEP (Appendix A), the NJDEP outlined its requirements for Fort Monmouth landfills:

- NJDEP stated that surface soils on all the landfills contain contaminants at concentrations exceeding New Jersey Soil Remediation Standards (SRS), and some of these contaminants appear to be associated with specific waste materials such as PCBs. PCBs have not been detected in M-14 Landfill surface soils.

- NJDEP stated that in locations where SRSs are exceeded, the NJDEP would accept placement of an additional one-foot-thick clean soil cover to eliminate direct contact.

Existing areas of exposed waste deposits must either be removed or properly re-graded and covered with 1-2 feet of clean soil cover. The NJDEP also stated that it would verify that the NJDEP Division of Solid and Hazardous Waste (DSHW) would accept one additional foot of soil cover as a final cover for the landfills.

- NJDEP DSHW requires evaluation of the landfills for methane gas generation and installation of passive or active gas venting systems as necessary. NJDEP stated that Fort Monmouth must perform a methane gas evaluation for each landfill or present existing documentation and data that conclusively show absence of subsurface methane gas at each landfill. In addition, deed notices would be required for all landfills due to the documented presence of waste deposits, even if NFA status was achieved.

2.3.8 2010 Sanitary Landfill Minor Disruption Approval

In September 2010, NJDEP granted approval of a Sanitary Landfill Minor Disruption Permit (Permit No. LCB100002) for conducting remedial investigation activities at the nine Fort Monmouth landfills (Appendix A). The minor disruption activities approved by the NJDEP include soil borings, soil sampling, test pits, installation of piezometers and monitoring wells, injection of chemical and biological oxidation agents to enhance ground water remediation, and methane gas surveys. The approval was granted with a five-year expiration date.

2.3.9 2010 NJDEP Regulatory Requirements for Landfills

In a letter dated November 2010, NJDEP provided Appendix 1 of *NJDEP Regulatory Approach – Fort Monmouth Landfills* (Appendix A). The letter indicates that the NJDEP Solid and Hazardous Waste Program (SHWP) determined that NJDEP SRP will assume the lead regulatory role for Fort Monmouth. Appendix 1 provides a summary and discussion of all NJDEP regulatory requirements for the Fort Monmouth Landfills including surface water, sediment, landfill cover/near-surface soils, methane gas, deed notices, and operation and maintenance.

2.3.10 2010 Aerial Photograph Analysis

In 2010, the Army conducted an analysis of historical aerial photographs for Main Post landfills (Appendix A).

<u>May 2, 1957 Aerial Photograph</u>

A 1957 aerial photograph of Fort Monmouth reveals that additional buildings were constructed on the eastern side of the Main Post, as well as an oval running track towards the southern-central portion of the Main Post. An incinerator is depicted in the southeast corner of the Main Post boundary near Main Street. In the photograph, the M-3, M-4, M-5, and M-8 Landfills are visible on the northeastern portion of the Main Post. A small magazine area is noted on the figure, located slightly north of the current M-2 Landfill area on the southwestern section of the

Main Post. The surrounding area appears to be more developed, with less open space and additional residential housing.

May 13, 1963 Aerial Photograph

Changes in this aerial photograph are primarily noted for the M-3, M4, M-5, and M-8 Landfills, which consolidate all of the landfills into one area labeled "Site 1." An L-shaped wall appears to divide the M-8 and M-5 Landfills. Possible construction debris and light-toned surface are noted in the northwest portion of the M-5 Landfill. The M-2 Landfill is labeled as "Site 2 Poss Landfill". A small fill area is depicted behind the Gosselin housing area within the vicinity of the current M-14 Landfill.

December 6, 1969 Aerial Photograph

The 1969 photograph of Fort Monmouth shows several new buildings that still remain today: the theater (Building 1215), bowling alley (Building 689), and Buildings 361, 362, and 363. The "Site 1" area that encompasses the M-3, M-4, M-5, and M-8 landfills shows a defined boundary for the M-8 Landfill and is now labeled as a landfill. Three new fill areas have been noted on the figure: (1) an area located within a small section of the current M-18 Landfill; (2) an additional fill area in the western portion of the M-12 Landfill; and (3) a small fill area located south of the 750 area.

March 13, 1974 Aerial Photograph

The 1974 photograph of Fort Monmouth reveals minor changes to the installation. The figure depicts the Main Post from the M-2 and M-3 Landfills to Oceanport Avenue. The M-2, M-3, M-8, M-12, M-14, and M-18 Landfills seem to be undisturbed and vegetated.

3.0 REMEDIAL ACTIVITIES

Based on information requested by NJDEP in their correspondence letters, the findings detailed in Versar's October 2003 *RIR and Sediment Quality Evaluation for the M-14 Landfill*, March 2004 *RIR for Near-Surface Soils*, August 2005 RIR, and previous work conducted by Weston in 1995, the Army conducted additional RI activities at the M-14 Landfill, including landfill boundary delineation activities and installation of monitoring wells.

3.1 Landfill Boundary and Near-Surface Soil Delineation Activities

In accordance with the NJDEP's August 19, 2008 approval letter, in December 2008, the Army conducted landfill boundary delineation activities to refine the dimensions of the M-14 Landfill. The landfill boundary delineation study involved advancement of test pits and soil borings. Test pits and trenches were advanced around the known perimeter of the M-14 Landfill boundary at 31 locations (Figure 3-1). Trench logs and photographic documentation logs are provided in Appendix C. The landfill boundary delineation activities resulted in minor expansion of northern boundary of the M-14 Landfill (Figure 3-1).

In addition to conducing test pits, the Army collected soil samples to define the boundaries of M-14 Landfill and to characterize near-surface soil quality conditions between the landfill (non-residential) and single-family structures (residential area) to the north. From December 28, 1998 to May 13, 2010, in accordance to the NJDEP's *Technical Requirements* (N.J.A.C. 7:26:E), the Army characterized the near-surface soils via advancement of 203 soil borings across the M-14 Landfill (Appendix C). All soil samples were analyzed for SVOCs, VOCs, pesticides, PCBs, and TAL metals. All soil sampling activities, including waste disposal, were conducted in accordance with applicable Fort Monmouth Standard Operating Procedures (Appendix D), which comply with the most current version of the NJDEP's *Field Sampling and Procedures Manual*.

Using a two-inch Geoprobe® Macrocore sampler, 518 soil samples were collected from the 203 soil borings. The soil boring locations were established in a grid-like pattern within the previously designated boundaries of the M-14 Landfill. Each soil sample, except those collected for VOC analysis, were collected between 0-12 inches bgs. Soil samples collected for VOC analysis were collected from 12-24 inches bgs since surface soils do not retain volatile constituents over time. Laboratory analyses of the soil samples collected were conducted by the Fort Monmouth Environmental Testing Laboratory (FMETL), a New Jersey certified laboratory. A summary of the soil sample collection information and analyses performed is provided in Appendix C.

Results of the December 28, 1998 - May 13, 2010 soil sampling program are discussed in Section 5.1 of this RIRA.

3.2 Monitoring Well Installation Activities

In accordance with the NJDEP's July 25, 2007 correspondence letter, during the current reporting period (2nd Quarter 2001 - 3rd Quarter 2010), the Army installed an upgradient monitoring well along the western border of the M-14 Landfill. Monitoring well M-14MW18 was installed in July 2010. Ground water samples collected from monitoring well M-14MW18 were analyzed for TCL+30 and TAL metals. Ground water sampling results are discussed in Section 5.2. The monitoring well log, permit, and record are provided in Appendix E.

Seven ground water monitoring wells (M14-MW18, M14-MW19, M14-MW20, M14-MW21, M14-MW22, M14-MW23, and M14-MW24) currently comprise the quarterly ground water monitoring program. The locations of all seven monitoring wells at M-14 Landfill are presented in Figure 3-2.

4.0 MONITORING AND SAMPLING ACTIVITIES

As part of the Long Term Monitoring (LTM) program implemented at the M-14 Landfill, quarterly ground water monitoring and surface water sampling was conducted from the 2nd Quarter 2001 - 3rd Quarter 2010. Ground water samples were collected from seven monitoring wells (M-14MW18, M-14MW19, M-14MW20, M-14MW21, M-14MW22, M-14MW23, and M-14MW24). Static depth-to-water was measured to determine ground water elevations for all seven monitoring wells for each ground water monitoring event.

Surface water samples were collected from 15 locations (SS-03, SS-05, SS-09, SS-11, SS-12, SS-13, SS-14, SS-15, SS-19, SS-21, SS-22, SS-24, SS-26, SS-27 and SS-28) across Fort Monmouth's Main Post. The nearest upstream sampling point from the M-14 Landfill is SS-19. The nearest downstream sampling point from the M-14 Landfill is SS-9.

Sampling was conducted by the Army in accordance with the established protocols as described in the Fort Monmouth SOPs and the NJDEP's most recent *Field Sampling and Procedures Manual*. Applicable Fort Monmouth SOPs are provided in Appendix D.

In November 2004, based on results of long-term ground water monitoring data, the Army requested a reduction in ground water analysis for samples collected from M-14 Landfill monitoring wells. On November 16, 2004, in an email correspondence to the Army, the NJDEP approved the reduction of ground water sample analysis to VOCs and TAL metals only (Appendix A).

Refer to Appendix F for ground water details and Appendix G for surface water details. Laboratory analyses of the samples were conducted at the FMETL, a New Jersey-certified laboratory (Certification No. 13461).

4.1 Ground Water Monitoring

During each round of the ground water sampling, depth-to-water measurements were collected at each monitoring well and recorded with an accuracy of 0.01 foot. Depth-to-ground water measurements for the last eight quarters of ground water sampling are presented in Table 4-1. During the current reporting period, separate phase product was not observed in any of the seven M-14 Landfill monitoring wells.

Ground water contour maps were generated for the 1st Quarter 2010 through the 3rd Quarter 2010 (Figures 4-1 through 4-3). Ground water was encountered at the M-14 Landfill at depths ranging from 5.84 feet to 7.66 feet bgs, grading towards Husky Brook. Starting in 2010, depth-to-water measurements were collected for the entire Main Post in lieu of site-specific measurements in order to provide a more accurate representation of ground water elevation. Depth-to-water measurements are summarized quarterly in Appendix F. NJDEP Contour Map Reporting Forms are also presented in Appendix F for each quarterly sampling event.

The contour maps indicate that shallow ground water underlying the M-14 Landfill consistently flows towards Husky Brook. Significant variations in ground water flow conditions were not observed during the current monitoring period.

4.2 Ground Water Sampling

Quarterly ground water sampling of the seven M-14 Landfill monitoring wells was conducted by the Fort Monmouth DPW.

Sampling equipment was decontaminated before and after each use. Following collection, the ground water samples were placed in laboratory-supplied bottleware. Sample containers were labeled, sealed, packed in ice, and transported to the FMETL under proper chain-of-custody procedures.

Appendix F includes all associated ground water data, tables and figures for each sampling event. Appendix F also includes ground water elevation summaries and ground water contour maps. Depth-to-water measurements were collected on a post-wide basis starting with the 1st Quarter 2010. Considering the much larger number of data points, post-wide data are considered to be better representations of ground water conditions. Contour Map Reporting Forms, Isoconcentration Maps, Isoconcentration Summaries, and full laboratory analytical data are also provided in Appendix F. Analytical results are discussed in Section 5.2.

4.3 Surface Water Sampling

During the current reporting period, surface water sampling was conducted by the Fort Monmouth DPW as part of the base-wide surface water sampling program. A total of 105 surface water samples were collected in seven rounds of sampling from 15 locations (SS-03, SS-05, SS-09, SS-11, SS-12, SS-13, SS-14, SS-15, SS-19, SS-21, SS-22, SS-24, SS-26, SS-27 and SS-28). A Surface Water Sample Location Map is provided as Figure 4-4. The samples were analyzed by the FMETL. The results of these analyses are discussed in Section 5.3.

Sampling equipment was decontaminated before and after each use. Surface water samples were collected and placed in laboratory-supplied bottleware. Sample containers were labeled, sealed, packed in ice, and transported to the FMETL under proper chain-of-custody procedures.

All surface water sampling data along with supporting data are presented in Appendix G, including copies of the chain-of-custody forms, laboratory analytical data, a summary of surface water sampling activities for Surface Water (Rounds 1 through 56) for all sampling points, sampling rounds, sample identifications, stream sampling locations, collection/analysis dates, analytical parameters, and analytical methods.

4.4 Types of Waste Generated and Disposal Methods

The waste types generated by the sampling activities included polyethylene tubing, Teflon® bailers, mason string, and personal protective equipment (PPE). The tubing, bailers, string, PPE, purge water, and decontamination solutions were properly disposed offsite.

5.0 SITE ANALYTICAL RESULTS

This section includes a summary discussion of the chemical characterization of the M-14 Landfill based on soil sampling and the seven most recent quarterly rounds of ground water and surface water samples collected and analyzed during the current reporting period.

5.1 Landfill Boundary and Near-Surface Soil Sampling Activities

From December 23, 1998 to May 13, 2010, 518 soil samples were collected from 203 soil borings at the M-14 Landfill. Soil analytical results were compared to the NJDEP's November 4, 2009 Soil Remediation Standards (N.J.A.C. 7:26D), as per Attachment 1 of NJDEP's November 2010 Letter: *Regulatory Approach to Fort Monmouth Landfills*. Soil analytical data tables for the M-14 Landfill are provided in Appendix C.

VOCs

No VOCs exceeded NJDEP NRDCSRS.

SVOCs

The following SVOCs were detected at concentrations exceeding NJDEP NRDCSRS in at least one soil sample: benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene).

Benzo(a)anthracene was detected at concentrations exceeding the NJDEP NRDCSRS of 2.0 mg/kg in six soil samples. Concentrations ranged from 2.4 mg/kg at B-8 (6-12") and B-114 (6-12") to 27.0 mg/kg at B-60 (6-12").

Benzo(a)pyrene was detected at concentrations exceeding the NJDEP NRDCSRS of 0.2 mg/kg in twenty soil samples. Concentrations ranged from 0.24 mg/kg at B-11 (6-12") and B-43 (6-12") to 26 mg/kg at B-60 (6-12").

Benzo(b)fluoranthene was detected at concentrations exceeding the NJDEP NRDCSRS of 2.0 mg/kg in six soil samples. Concentrations ranged from 2.0 mg/kg at B-112 (6-12") to 23.0 mg/kg at B-60 (6-12").

Benzo(k)fluoranthene was detected at concentrations exceeding the NDJEP NRDCSRS of 23.0 mg/kg in soil sample B-60 (6-12") at a concentration of 25 mg/kg.

Dibenz(a,h)anthracene was detected at concentrations exceeding the NJDEP NRDCSRS of 0.2 mg/kg in seven soil samples. Concentrations ranged from 0.21 mg/kg at B-25 (6-12") to 2.05 mg/kg at D-05 (0-6").

Indeno(1,2,3-cd)pyrene was detected at concentrations exceeding the NJDEP NRDCSRS of 2.0 mg/kg in three soil samples. Concentrations ranged from 4.1 mg/kg at D-05 (0-6") to 13 mg/kg at B-60 (6-12").

Metals

Two metals (arsenic and lead) were detected at concentrations exceeding NJDEP NRDCSRS in at least one soil sample. These analytical results are summarized in Tables 5-1 through 5-7.

Arsenic was detected at concentrations exceeding NJDEP NRDCSRS of 19 mg/kg in 58 soil samples. Concentrations ranged from 19.2 mg/kg at C-11 (0-6") to 168 mg/kg at B-28 (6-12").

Lead was detected at concentrations exceeding the NJDEP NRDCSRS of 800 mg/kg in one soil sample D-37 (0-6") at a concentration of 946 mg/kg.

5.1.1 Soil Summary

No VOCs, pesticides, or PCBs were detected at concentrations greater than NRDCSRS. Thus, VOCs, pesticides and PCBs are not considered soil COCs at the M-14 Landfill. Although arsenic and lead concentrations exceeded NJDEP NRDCSRS, these metals are not considered COCs because they are naturally-occurring within Fort Monmouth soils. Refer to the Background Metals Evaluation provided in Section 6.0 of this RIRA for additional details regarding naturally-occurring metals in Fort Monmouth soils.

The six SVOCs [benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(k)fluoranthene, dibenz(a,h)anthracene, and indeno(1,2,3-cd)pyrene] are considered soil COCs for M-14 Landfill as they exceed both the NJDEP NRDCSRS and Maximum Background Concentrations (MBC) established for soils at the Main Post.

- ***Benzo(a)anthracene*** is considered a COC because it was detected at concentrations greater than the MBC of 0.65 mg/kg in six of the six samples where benzo(a)anthracene exceeded NJDEP NRDCSRS (2 mg/kg).
- ***Benzo(a)pyrene*** is considered a COC because it was detected at concentrations greater than the MBC of 0.6 mg/kg in 10 of the 21 samples where benzo(a)pyrene exceeded NJDEP NRDCSRS (0.2 mg/kg).
- ***Benzo(b)fluoranthene*** is considered a COC because it was detected at concentrations exceeding the MBC of 0.9 mg/kg in six samples where benzo(b)fluoranthene exceeded NJDEP NRDCSRS.
- ***Benzo(k)fluoranthene*** was detected in only one sample at a concentration greater than the NJDEP NRDCSRS and the MBC of 0.43 mg/kg. Due to the infrequency and

magnitude of exceedance in soil samples, benzo(k)fluoranthene is not considered to be a COC.

- ***Dibenz(a,h)anthracene*** is considered a COC because it was detected at concentrations greater than the MBC of 0.079 mg/kg in seven samples where dibenz(a,h)anthracene exceeded NJDEP NRDCSRS.
- ***Indeno(1,2,3-cd)pyrene*** is considered a COC because it was detected at concentrations greater than the MBC of 0.46 mg/kg in three samples where indeno(1,2,3-cd)pyrene exceeded NJDEP NRDCSRS.

5.1.2 Quality Assurance/Quality Control - Soil

Quality assurance/quality control (QA/QC) samples including samples duplicates, field blanks and trip blanks, were collected in accordance with the version of the NJDEP *Field Sampling Procedures Manual* in effect at the time sampling was conducted.

5.2 Ground Water Sampling Results

Analytical results from each of the seven monitoring wells at the M-14 Landfill for are summarized in Tables 5-1 through 5-7. Ground water summary tables include detected analytical results and are divided by monitoring well numbers and sampling date. The characterization of ground water quality at the M-14 Landfill consists of quarterly ground water sampling events conducted from 2nd Quarter 2001 – 3rd Quarter 2010. Ground water analytical results are compared to NJDEP GWQS and are presented in three different tabs reflecting changes to NJDEP GWQS. The first set of data is compared against the January 7, 1993 criteria; the next is when a criterion change occurred on November 7, 2005, followed by another criterion change on July 27, 2007.

The results in the ground water summary tables include analyte detections including exceedances of NJDEP GWQS, which are bolded and shaded. Detections are presented in the ground water sampling result summary tables as follows:

- Xylenes are reported as total xylenes (the sum of *o*-xylene and *m,p*-xylenes).
- TICs are added and reported as a total concentration for the sum of TICs detected for VOCs and SVOCs.
- Duplicate samples are included after the respective primary sample.
- Low flow sampling method results are identified as "LF."
- A "J" value is a concentration exceeding the method detection limit (MDL) but less than the reporting limit (RL) for VOCs, SVOCs, and pesticides/PCBs.
- Estimated Results (ER) are concentrations exceeding the MDL and less than the RL for metals.

- A "B" value is a compound detected in the sample and its associated blank sample.
- Sample suites that were discontinued are recorded in the footnotes along with a date of NJDEP Case Manager approval.

If a particular sample suite or analyte was not detected in a monitoring well, the suite/analyte is not presented in the monitoring well summary table.

5.2.1 VOCs

Throughout the current reporting period, no VOCs were detected in ground water samples at concentrations exceeding NJDEP GWQS.

5.2.2 VO TICs

Throughout the current reporting period, no VOC TIC concentrations were detected in ground water samples in excess of the NJDEP GWQS of 100 µg/L for individual compounds or 500 µg/L for total TIC concentrations.

5.2.3 SVOCs

Throughout the current reporting period, no SVOCs were detected in ground water samples at concentrations exceeding NJDEP GWQS.

5.2.4 SVO TICs

Throughout the current reporting period, no SVO TIC concentrations were detected in ground water samples in excess of the NJDEP GWQS of 100 µg/L for individual compounds or 500 µg/L for total TIC concentrations.

5.2.5 Pesticides and PCBs

Throughout the current reporting period, no pesticides or PCBs were detected at concentrations exceeding NJDEP GWQS.

5.2.6 Metals

During the last eight quarterly sampling events conducted from October 2008 to August 2010, eight metals were detected in ground water samples at concentrations exceeding NJDEP GWQS.

Antimony was detected at concentrations exceeding the NJDEP GWQS of 6.0 µg/L at six monitoring wells. Concentrations ranged from 6.5 µg/L (Low-flow #4 – round 55) in M-14MW21 to 23.1 µg/L (sampling round 38) in M-14MW24.

Arsenic was detected at concentrations exceeding the NJDEP GWQS of 3.0 µg/L at seven monitoring wells. Concentrations ranged from 3.27 µg/L (sampling round 49) in M-14MW24 to 95.6 µg/L (sampling round 38) in M-14MW24.

Beryllium was detected at a concentration exceeding the NJDEP GWQS of 1.0 µg/L in only one round of sampling (1.09 µg/L in sampling round 38) at one monitoring well (M-14MW23).

Cadmium was detected at concentrations exceeding the NJDEP GWQS of 4.0 µg/L at two monitoring wells. Concentrations ranged from 5.82 µg/L (sampling round 42) in M-14MW23 to 145 µg/L (sampling round 56) in M-14MW22.

Lead was detected at concentrations exceeding the NJDEP GWQS of 5.0 µg/L at four monitoring wells. Concentrations ranged from 5.41 µg/L (sampling round 39) in M-14MW24 to 9.96 µg/L (sampling round 50) in M-14MW22.

Nickel was detected at a concentration exceeding the NJDEP GWQS of 100.0 µg/L in only one round of sampling conducted at one monitoring well. Nickel was detected at 205 µg/L (sampling round 56) in M-14MW22.

Selenium was detected at concentrations exceeding the NJDEP GWQS of 40.0 µg/L in five rounds of sampling conducted at six monitoring wells. Concentrations ranged from 41.2 µg/L (sampling round 55) in M-14MW19 to 119 µg/L (sampling round 44) in M-14MW24.

Thallium was detected at a concentration exceeding the NJDEP GWQS of 2.0 µg/L in one round of sampling at one monitoring well. Thallium was detected at 4.02 µg/L (sampling round 37) in M-14MW24.

5.2.7 Ground Water Summary

Figure 5-1 (Ground Water Contaminants of Concern Distribution Map) depicts all analytes that exceeded NJDEP GWQS for the eight most recent ground water sampling events. Only metals (antimony, arsenic, beryllium, cadmium, lead, nickel, and thallium) were detected at concentrations exceeding NJDEP GWQS.

5.2.8 Ground Water – QA/QC

Quality assurance and quality control (QA/QC) samples were collected in accordance with the current version of the NJDEP's *Field Sampling Procedures Manual* in effect at the time sampling was conducted. All ground water samples were analyzed by the FMETL within the prescribed holding time requirements for the analytical method. Ground water QA/QC sample results are provided in the relevant lab packages in Appendix F.

M-14 Ground Water Data Validation

Tetra Tech EM Inc. (Tetra Tech) conducted data validation for the M-14 Landfill. Data was evaluated for the following criteria: data completeness; sample preservation, receipt, and holding times; gas chromatography and mass spectrometry (GC/MS) instrument performance checks; initial and continuing calibration; calibration verification; field, trip, and laboratory blanks; inductively coupled plasma – interference check sample (ICP-ICS); system monitoring compounds (surrogates); matrix spike/matrix spike duplicates (MS/MSDs); laboratory duplicate sample analysis; ICP serial dilution; field duplicates; laboratory control samples (LCSs); dilution; re-extraction and reanalysis; internal standards; target analyte identification; analyte quantitation; and reported detection limits. Data validation packages are provided in their respective appendices.

- Tetra Tech conducted data validation of the analytical results for six groundwater samples, one field duplicate, one rinsate blank, and one trip blank that were collected at the M-14 Landfill on November 20, 2009 as part of the fourth quarter 2009 long-term monitoring project. Tetra Tech concluded the overall quality of this data package was acceptable. All data can be used as qualified.

- Tetra Tech conducted data validation of the analytical results for six groundwater samples, two field duplicates, two field blanks, and two trip blanks that were collected at the M-14 Landfill on June 4 and 7, 2010 as part of the second quarter 2010 long-term monitoring project. Tetra Tech concluded the overall quality of this data package was acceptable. All data can be used as qualified.

5.3 Surface Water Sampling Results

Quarterly surface water samples were collected at 15 locations during the current sampling period (Surface Water Sampling Rounds 50 through 56). The nearest upstream sampling point from the M-14 Landfill is SS-19. The nearest downstream sampling point from the M-14 Landfill is SS-09. Results for surface water samples from inception of LTM are summarized in Appendix G. Surface water summary tables include detected analytical results for the surface water sample locations and are divided by surface water sample numbers and sampling dates.

From March 2009 through September 2010, seven quarterly surface water sampling events were conducted. Surface water sampling results from the base-wide sampling program were compared to NJDEP Freshwater SWQS. Concentrations of VOCs, metals, and wet chemistry exceeding NJDEP Freshwater SWQS are summarized in Appendix G. Surface water contaminant distributions with time are presented in Appendix G. The results of the current surface water sampling events are discussed below.

The results in the surface water summary tables include analyte detections as well as

exceedances of the NJDEP Freshwater SWQS, which are bolded and shaded. VOCs, metals, and wet chemistry parameters are presented as required to summarize results for detected parameters. Detections are presented in the surface water sampling result summary tables as follows:

- Xylenes are reported as total xylenes (the sum of *o*-xylene and *m,p*-xylenes).
- TICs are added and reported as a total concentration for the sum of TICs detected for VOCs.
- Duplicate samples are included after the respective primary sample.
- A "J" value is a concentration exceeding the MDL but less than the RL for VOCs.
- Estimated Results "ER" are concentrations exceeding the MDL and less than the RL for metals.
- A "B" value is a compound detected in the sample and its associated field blank sample.
- If a particular sample suite or analyte was not detected in a surface water sample location, the suite/analyte is not presented in the summary table.

5.3.1 VOCs

During surface water sampling events conducted during the current reporting period, four VOCs (bromodichloromethane, PCE, TCE, and vinyl chloride) were detected at concentrations exceeding SWQS.

Appendix G includes a summary of the analytical results which exceeded NJDEP SWQS during the current reporting period.

5.3.2 TICs

During the current reporting period, VO TICs were periodically detected at seven of the 15 surface water sampling locations. For comparison purposes, concentrations were compared to the GWQS as there are no SWQS for VO TICs.

Surface water TICs did not exceed either the NJDEP GWQS of 100 µg/L for an individual compound or 500 µg/L for total TIC concentrations during this reporting period. Appendix G includes a summary of the analytical results for the surface water TICs during this reporting period.

5.3.3 Metals

Antimony, arsenic, lead, and mercury were detected at concentrations that exceeded their respective NJDEP SWQS.

5.3.4 Pesticides and PCBs

Pesticides and PCBs were not analyzed in surface water samples collected during the current reporting period.

5.3.5 Surface Water Summary

During surface water sampling events conducted during the current reporting period, four VOCs (bromodichloromethane, PCE, TCE, and vinyl chloride) were detected at concentrations exceeding SWQS. Antimony, arsenic, lead, and mercury were detected at concentrations exceeding NJDEP SWQS.

During the current reporting period, surface water samples collected at the nearest upstream sampling point (SS-19) from the M-14 Landfill exceeded NJDEP SWQS for arsenic, bromodichloromethane, and lead. Surface water samples collected at the nearest downstream sampling point (SS-09) from the M-14 Landfill exceeded NJDEP SWQS for arsenic and lead.

5.3.6 Surface Water – QA/QC

To verify the reliability of surface water analytical results, Brinkerhoff reviewed the holding times for each sample and the results of the analyses of nine method blanks, seven trip blanks, seven field blanks, and seven field duplicate samples for the surface water samples. The discussion below is based upon QA/QC for the VOC surface water samples. Samples were analyzed by the FMETL within the prescribed holding time requirements for the analytical method.

Method Blanks

Laboratory method blanks accompanied each set of surface water samples for each surface water sampling event. These method blanks consisted of laboratory-deionized water that is processed identically to the samples and analyzed with the sample batch. A total of nine VOC method blanks were analyzed with the base wide surface water samples.

No COCs were detected in the method blank samples.

Trip Blanks

Seven trip blanks were included as part of the base-wide surface water sampling program to document that VOCs were not introduced into the samples during the handling process. The trip blanks were prepared by the FMETL and consisted of sample bottles filled with laboratory-deionized water. The trip blanks remained with the sample bottles in coolers and were returned to the laboratory for analyses along with the surface water samples.

Methylene chloride was detected in one of the seven trip blanks at a concentration of 15.28 µg/L, which exceeds the NJDEP Freshwater SWQS of 2.5 µg/L, but is in compliance with the saline SWQS of 310 µg/L. Methylene chloride is a common laboratory contaminant.

Field Blanks

During each day's sampling activities, one field blank sample was collected to document equipment decontamination procedures. A total of seven field blanks were collected during the base-wide surface water sampling program. The field blanks were collected by pouring deionized water supplied by the laboratory over the equipment used for daily sampling activities. The water was collected in clean laboratory-supplied containers and submitted for analysis along with the surface water samples.

Methylene chloride was detected in one of the seven trip blanks at a concentration of 2.18 µg/L, which is in compliance with the NJDEP Freshwater SWQS of 2.5 µg/L. Methylene chloride is a common laboratory contaminant.

Duplicate Samples

Seven field duplicate samples were also collected during the base-wide surface water sampling events to verify the consistency of the entire sampling and analytical procedures. The results for the duplicate samples were similar to those collected for the original samples. The RPDs for the duplicate sample analyses ranged from 0 to 21.51 percent; however, the average RPD for the seven duplicates was 13.65 percent. Based upon average RPDs, the QA/QC sampling results indicate a high level of precision.

Surface Water Data Validation

Tetra Tech conducted data validation for the Main Post Surface Water Sampling. Data was evaluated for the following criteria: data completeness, sample preservation, receipt and holding times, GC/MS instrument performance checks, initial and continuing calibration, calibration verification, field, trip, and laboratory blanks, ICP-ICS, system monitoring compounds (surrogates), MS/MSDs, laboratory duplicate sample analysis, ICP serial dilution, field duplicates, LCSs, dilution, reextraction and reanalysis, internal standards, target analyte identification, analyte quantitation, and reported detection limits. Data validation packages are provided in Appendix G.

- Tetra Tech conducted data validation of the analytical results for fifteen surface water samples, one field duplicate, one field blank, and one trip blank that were collected at from stream sampling points (abbreviated to "SS" in the sample designations) on December 7, 2009. The overall quality of this data package was acceptable. Rejection of data was not required for this data package. The VOC data were qualified due to minor

calibration irregularities and results less than the laboratory RLs but greater than the MDLs. Metals results were qualified for calibration verification irregularities, blank contamination, a result greater than the linear range of the instrument, and results less than the laboratory RLs but greater than the MDLs. All data can be used as qualified.

- Tetra Tech conducted data validation of the analytical results for 15 surface water samples, one field duplicate, one trip blank, and one field blank, that were collected on June 22, 2010 as part of the 2nd Quarter 2010 LTM project. Tetra Tech concluded that the overall quality of the data was acceptable. No analytical results were rejected. All data can be used as qualified.

6.0 BACKGROUND METALS EVALUATION

Historically, ground water samples from monitoring wells throughout Fort Monmouth's Main Post and the Charles Wood Area have periodically displayed concentrations of metals that exceed NJDEP GWQS. Some of the metals have been retained as COCs while characterization has continued. However, it has long been believed that the metal detections represent materials derived from the native soil as a background condition in the local region.

Brinkerhoff Environmental Services (2011) noted the likelihood that metal results reflected the presence of high turbidity in samples (see Appendix H). In addition, the analysis of glauconitic clay (see Appendix H) indicates that the clay contains a metal fingerprint that mirrors that found in turbid ground water samples, suggesting the fines from the native clays are the source of the turbidity and that the metals are derived from acid extraction of the metals on those fines when subjected to the preservatives added to the sample vials.

The Army has conducted additional analysis of available data and concludes that the metals heretofore designated as COCs in ground water are, in fact, native materials associated with clay fines in the samples. The following describes the approach taken and the conclusions drawn from the results of the analyses.

6.1 Evaluation Approach

In the past, each site at Fort Monmouth has been evaluated on its own merits with respect to COCs and risk. However, it has become very clear that the apparent metals issue is ubiquitous and would benefit from a base-wide analysis. Pursuant to that, a review was made of all historical groundwater sampling data to help put metal results in perspective. In the Brinkerhoff background analysis (2011), it was concluded that there were no sources for any of the metals observed in ground water, with the possible exception of lead. Because there were potential sources of lead present at Fort Monmouth (but not specifically associated with any individual site), Brinkerhoff chose not to rule out the possibility that some of the metals found in ground water could be the direct result of a release. At the same time, Brinkerhoff found a direct correlation between arsenic concentrations and lead concentrations, despite there being no potential source of arsenic releases. The obvious implication of that finding is that lead, as well as arsenic, arises from its presence in native soil. As a consequence, the Army has focused its analysis primarily on lead.

The review focused on the following areas:

- Nature of apparent sources
- Relationship of metals levels to turbidity
- Extreme variability in field duplicate results
- History of atypical spikes

6.1.1 Nature of Apparent Sources

A review of monitoring data over the life of the environmental restoration program at Fort Monmouth reveals that virtually every monitoring well at one time or another has had a metal concentration that has exceeded NJDEP GWQS. Given the diverse nature of activities and the location of the monitoring wells, this suggests a common factor across sites other than the activities that might have resulted in releases. Specific to lead contamination, sites with heating oil tanks and lime pits are unlikely sources of a release. Not only is lead not present as an additive in heating oil, but the characteristics of the lime pit should reduce the solubility of lead, not increase it. Lead is mobilized by acidity, not by basic conditions.

When the review is expanded to all metals, there is a consistent pattern of observations despite the nature of the Army's activities as seen in Table 6-1. Moreover, the metals observed (antimony – Sb; arsenic – As; beryllium – Be, cadmium – Cd, chromium – Cr; lead – Pb; and nickel – Ni) are all present in glauconitic clay. Metal observations in ground water are consistent, despite the disparate nature of the Army's activities at the sites being monitored.

Table 6-1
Metal Observations in Ground Water Are Consistent, Despite the Disparate Nature of the Army's Activities At the Sites Being Monitored

Site	Release Type	Location	Other COCs	Metals > NJGWQS (Bkgd)
FTMM-14, M-14 Landfill	Landfill	Main Base, Central		Sb, As, Be, Cd, Pb, Th
FTMM-03, Landfill M-3	Landfill	Main Base, North Central	VOC	Sb, As, Cd, Pb
Building 750	Heating Oil USTs	Main Base. South Central		Sb, As, Be, Cd, Cr, Pb, Ni
FTMM-18, 54, 55, 62	Landfill, USTs, Fuel area	Main Base, North Central	Benzene	Sb, As, Be, Cd, Pb
FTMM-25, Landfill CW-3A	Landfill	Charles Wood, South		Sb, As, Be, Cd, Cr, Pb
FTMM-28, Pesticide Spill Location	Pesticide Spill, USTs Fuel Area	Charles Wood, Central		As, Pb, Cd, Sb, Sl, Th
FTMM-04, Landfill M-4	Landfill	Main Base, West Central		Sb, As, Be, Cd, Pb, Th
FTMM-12, M-12 Landfill	Landfill	Main Base, Central		Sb, As, Be, Cd, Pb, Th
FTMM-66, Building	Heating Oil	Main Base,	Methyl	Sb, As, Cd, Pb

Site	Release Type	Location	Other COCs	Metals > NJGWQS (Bkgd)
866	AST	South Central	Napthalene, Benzene, BEHP	
FTMM-58, Building 2567	Active Gas Station	Charles Wood, East Central	Tert Butyl Alcohol	Sb, As, Pb
FTMM-56, Buildings 80-166	Heating Oil UST	Main Base, East	Chlordane, DDD, DDE	Sb, As, Be, Cd, Pb, Th
FTMM-22, Building CW-1	Lime Pit	Charles Wood, West	TCE	Sb, As, Pb
FTMM-57, Building 108	Heating Oil UST	Main Base, East		Sb, AS, Pb

6.1.2 Relationship of Metal Levels to Turbidity

Brinkerhoff Environmental Services' *Report on Background Metals* (2011) notes in Section 4.2 that there has been a historic problem with turbid samples and the subsequent dissolution of metals from native soil by the nitric acid preservative used on samples intended for metals analysis. In a background study of the glauconite-rich soil at Fort Monmouth, researchers noted concentrations of 16 mg/kg lead (March 9, 2011 letter from U.S. Army to Larry Quinn). Turbidity is exacerbated by purge techniques in formations with fine soil particles, but can also be a problem with low-flow sampling as noted in Tetra Tech's January 2010 Data Validation Report in which some field duplicates had RPDs for metals that exceeded QC criteria (e.g., 80MW03 on 2/24/2010).

Turbidity data have not been reported for most historic samples. However, turbidity has been measured since implementation of low-flow sampling techniques in 2010. In general, samples should have turbidity < 5 units for a sample to yield results representative of dissolved metals. The data presented in Table 6-2 summarize turbidity levels for samples taken from various sites at Fort Monmouth in 2010. Clearly, turbidity remains a problem, despite the use of low-flow sampling. Occurrence of turbidity in excess of 5 NTU in 2010 samples have continued despite the use of low-flow sampling techniques. Turbidity data for FTMM-28 in the second quarter sampling of 2010 were as follows: MW-01 – 4.48 NTU; MW02 – 38 NTU; MW-03 – 6.14 NTU; and MW-34 – 10.2 NTU. The turbidity data for FTMM-28 for the third quarter of 2010 were as follows: MW-01 – 9.36 NTU; MW02 – 18.3 NTU; MW-03 – 4.12 NTU; and MW-34 – 9.81 NTU.

Table 6-2
Occurrence of Turbidity In Excess of 5 JTU in 2010 Samples Have Continued, Despite Use of Low Flow Sampling Techniques

Site	Turbidity (NTU) **Bold XX** – Value is in excess of 5 NTU										
	MW01	MW02	MW03	MW04	MW05	MW06	MW07	MW08	MW09	MW10	MW11

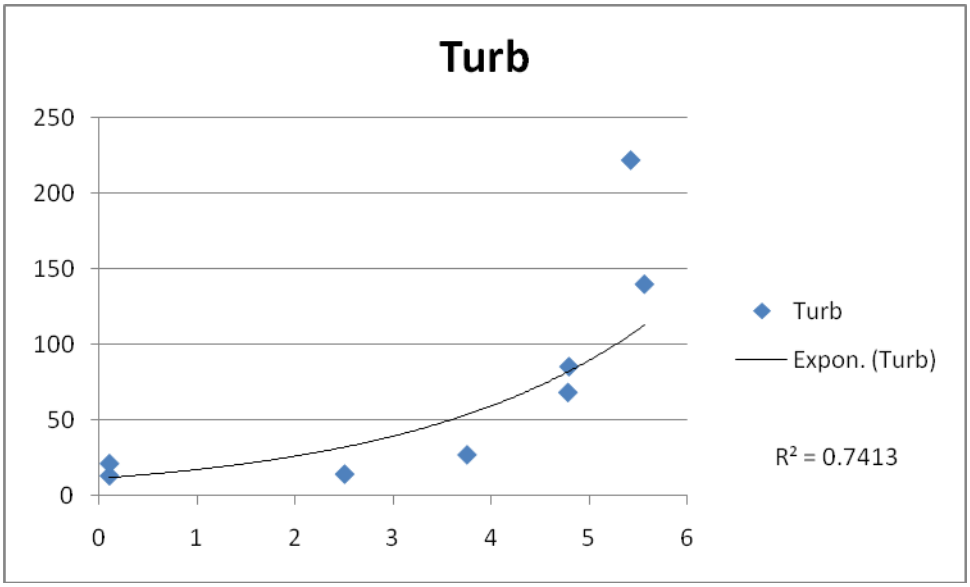
When the turbidity is high, there is a direct correlation between turbidity and lead concentrations as is evident from the data from Site FTMM-66 samples collected in May 2010 (Figure 6-1).

Figure 6-1
There is a Direct Correlation Between Turbidity and Lead Concentrations at FTMM-66 Using Low Flow Sampling Techniques



As one would expect, the introduction of low-flow sampling techniques has reduced metal concentrations reported in ground water samples at Fort Monmouth. A comparison of lead concentrations prior to and after implementation of the low-flow techniques is provided in Table 6-3. As is evident, lead concentrations decreased when low flow sampling was implemented. However, as presented in Table 6-2, turbidity issues are still present with low flow sampling and can still cause an apparent elevation in lead levels.

Table 6-3
There Has Been a Clear Reduction in Lead with Use of Low Flow Sampling Techniques, Despite Continued Presence of High Turbidity

6.1.3 Extreme Variability in Metal Content of Field Duplicate Samples

In accordance with standard quality control/quality assurance protocol, field duplicate samples were collected throughout the performance of monitoring work at Fort Monmouth. Pursuant to the Quality Assurance Project Plan for Fort Monmouth, whenever samples are found to have a

relative percent difference (RPD) of greater than 25% for metals, the data quality is suspect. An examination of the RPD values for ground water samples at Fort Monmouth reveals that a significant number of the duplicates collected from wells across the installation have RPD values well in excess of 25%.

Table 6-4
A Significant Percentage of the Field Duplicates Collected at Fort Monmouth Yielded RPD for Lead in Excess of the Quality Control/Quality Assurance Threshold Value of 25%

Site	Well	Date	Lead Concentration (ug/L)		RPD (%)

		4/2001	31	6.44	131
		8/2001	15.9	15.2	5

The presence of turbidity is the most common cause of poor RPD performance when metals are the analyte. Simply put, suspended solids that cause turbidity in water samples are heterogeneous by nature and when the sample is split, there is no way to divide them evenly so that both samples obtain the same amount of solids, let alone an evenly divided sampling of the different solid particle types that may be present. A single particle of mineral origin can have sufficient metal content to dramatically affect the RPD.

6.1.4 Occurrence of Atypical Spikes

Metals generally move slowly in ground water, both because of the slow velocity of the water itself and because of interactions with the soil that retard their movement. As such, time frames are sufficient for dispersion and diffusion to give rise to classic Gaussian plumes that display first order concentration gradients. When samples collected in sequential quarters differ in concentration by more than an order of magnitude, it suggests that at least one of the two values does not represent dissolved metal content and is more likely to be the result of acid extraction from suspended solids in the sample. Atypical spikes noted in historic monitoring results are presented in Table 6-5.

Table 6-5
Historical Data from Fort Monmouth Show Rapid Increases and Decreases in Lead Concentrations That Cannot Be Attributed to Dissolved Metals

Site	Well	Date	Lead Concentration (ug/L)		
			Preceding	Spike	Succeeding
FTMM-57	MW01	3-9/1999	90	125	11.2
		5-10/2002	6.91	28.3	4.88

6.2 Conclusion of Base-Wide Evaluation of Metals As Contaminants of Concern

The only consistent explanation for lead findings to date (and other metals as well) is that fine particles of glauconitic clay are suspended in many of the samples and yield metals when contacted with the acid preservative used for ground water samples. The applicability of each of these factors to individual sites at Fort Monmouth is summarized in Table 6-6.

Table 6-6
All Sites with Historic Lead Occurrences Have One or More Clear Markers Suggesting Turbidity is the Source of the Lead

Site and Use	Most Recent Lead Con Range in ug/L (date)	Percent of Low Flow Samples with Turbidity > 5 NTU	Affect of Low Flow (Ave Post/Pre)*	% of RPD** > 25 (Maximum RPD)*	# Atypical Spikes (Max Value in ug/L)
FTMM-12, M-14 Landfill	ND-9.23 (9/9/2010)			60% (194)	2 (9.96)
FTMM-03, Landfill M-3	ND-8.37 (9/7/2010)	50% (Q1) 62.5% (Q2)	0.59	100% (85)	
Building 750 – Heating Oil UST	ND (8/18/2010)		0.13		18 (612)

FTMM-57, Building 108, Heating Oil UST	ND-6.91 (8/19/2010)	75%	0.55	70% (197)	11 (163)

*Based on setting ND samples at 1 ug/kg
**If both duplicates were ND or if one was ND and the other <2 ug/L, the duplicate was not evaluated

Given the weight of evidence, the Army has concluded that metal detections in general, and lead specifically, are the direct result of acid leaching of suspended solids in ground water samples. Therefore, metals are not considered COCs. This is further supported by the location of the Wenonah Mount Laurel aquifer, which is approximately 125 feet bgs - too deep to be affected by the presence of these metals near ground surface. In addition, the sensitive receptor survey (Appendix I) indicated no domestic or irrigation wells are close enough to be adversely impacted by COC migration.

7.0 RECEPTOR EVALUATION

7.1 Sensitive Receptor and Well Search

A visual and documentary search of sensitive populations was performed by the Army and their subcontractor to identify potentially sensitive populations within 200 feet of Fort Monmouth's boundaries. The identification of said populations is in accordance with NJDEP statutory requirements. The Receptor Evaluation Report, NJDEP Sensitive Receptor Survey Form, and Sensitive Receptor Survey figure are provided in Appendix I.

Although the identified populations are within 200 feet of Fort Monmouth's boundaries, all of the environmentally-impacted locations are an appreciable distance from the fence line and in all cases exceed the 200-foot buffer established by NJDEP. In addition, site-specific utility maps were reviewed to identify any preferential pathways which could affect site contamination plumes. These maps are provided in Appendix I.

In addition to the sensitive receptors, the Army has included all identified off-site wells within 2,000 feet of Fort Monmouth's perimeter. No production wells were identified within 2,000 feet of Fort Monmouth's boundaries. The majority of off-site wells are monitoring wells associated with various remedial activities. A ground water model has been developed for Fort Monmouth, with the overall ground water flow pattern for the Main Post being easterly with a localized northeasterly component. Fort Monmouth is bounded by surface water bodies to the east and northeast. Domestic and/or irrigation wells to the east or northeast of the Main Post would not be impacted by activities conducted on the Fort Monmouth property.

Surface water bodies interact with ground water at Fort Monmouth. The interaction takes place in three basic ways: streams gain water from inflow of ground water through the streambed, streams lose water to ground water by outflow through the streambed, or both, gaining in some reaches and losing in other reaches. When ground water discharges into a surface water body, the elevation of the ground water table in the vicinity of the surface water body must be higher than the elevation of the stream water surface. Conversely, for surface water to seep to ground water, the elevation of the water table in the vicinity of the stream must be lower than the elevation of the stream water surface. The surface water bodies at Fort Monmouth (Oceanport and Parkers Creeks) may be gaining or losing depending upon the tidal cycle. Throughout the entire tidal cycle however, net results are that ground water inflows into the creeks, albeit at low flow rates. Figures depicting the surface water features, wetland areas, and stream bank stabilization areas in the vicinity of the Site are included in Appendix I.

7.2 Vapor Intrusion (VI) Investigation

The Army evaluated the requirements for a VI investigation in accordance with the NJDEP's Vapor Intrusion (VI) Guidance and *Technical Requirements*. As detailed in the NJDEP VI Guidance, three-stage assessment criteria were utilized to determine the applicability of VI

regulations. Site-specific ground water data from the seven most recent quarterly ground water sampling events were compared to the NJDEP generic VI screening levels.

Concentrations of COCs in ground water do not exceed the generic ground water screening levels (GWSL) presented in the NJDEP VI Guidance within 100 feet (specific to chlorinated solvents) of nearby buildings. According to the decision flow chart for VI, no investigation is required for the M-14 Landfill.

7.3 Baseline Ecological Evaluation (BEE)

Shaw Environmental, Inc. was contracted by the Army to conduct a Baseline Ecological Evaluation (BEE) for Fort Monmouth's Main Post and Charles Wood Areas. Sampling of multiple media was conducted in 2010. The final BEE was submitted in May 2011 and will be updated once comments are resolved with NJDEP.

7.4 Public Notification

In accordance with the Public Notification requirements in the *Technical Requirements* at N.J.A.C. 7:26E-1.4, the Army submitted a request to the NJDEP Site Remediation Program (SRP) dated June 17, 2010 to conduct an *Alternative Public Notification Plan*. This request was approved by the NJDEP in correspondence dated June 24, 2010. Copies of said correspondence are provided in Appendix I.

The *Alternative Public Notification Plan* includes newspaper advertisements being placed in local and county newspapers through the Asbury Park Press and The Link, all public notification documents being sent to the Municipal Clerk for each municipality in which the contaminated site is located, and to the local designated health official. The FTMM also established a local document repository for all reports produced regarding the site remediation areas of concern (AOCs) at Fort Monmouth. The repository is located at the Monmouth County Library in Shrewsbury, New Jersey where all reports are available for public review. All of these reports are also available online at http://www.pica.army.mil/FtMonmouth.

The Fort conducted two Open Houses in January of 2008 and January of 2009, during which times figures and data regarding all of the Fort's site remediation AOCs were on display. Fort environmental personnel were available to answer questions from the public. The Fort will conduct a third Open House should the need arise.

The Fort also operates a Restoration Advisory Board (RAB) which holds quarterly public meetings held by RAB members who are public citizens, not elected officials, selected from the surrounding towns. They review and comment on technical documents and plans relating to ongoing environmental investigations and restoration activities at the Fort. Members serve as liaisons with the community and are available to meet with community members and groups. The meetings are open to the public and notification of all meetings is provided in local

newspapers as well as by mail to all interested parties. All environmental projects subject to the *Technical Requirements* are presented to the RAB via this public forum. Examples of the media release and Affidavit are provided in Appendix I.

8.0 REMEDIAL ACTION PROGRESS

8.1 Costs of Remediation Incurred to Date

The total costs to date for the implementation of the remedial actions performed at the M-14 Landfill are approximately $X,XXX,XXX (Refer to Appendix J). This includes the Preliminary Assessment (PA) phase, SI, Remedial Investigation/Feasibility Study, LTM, and reporting (including RIRs and RIRAs).

8.2 Ground Water Conclusions

During the current reporting period (2nd Quarter 2001 – 3rd Quarter 2010), ground water sampling was conducted quarterly. For the last eight ground water sampling quarters (4th Quarter 2008 – 3rd Quarter 2010), only metals (antimony, arsenic, beryllium, cadmium, lead, nickel, and thallium) exceeded NJDEP GWQS. Metal detections in general, and lead specifically, are the direct result of acid leaching of suspended solids in ground water samples as discussed in depth in Section 6.0. Therefore, metals are not considered COCs at the M-14 Landfill. In addition, due to the extremely slow migration rates of metals in ground water, they pose little potential for migration. Since no COCs exceed NJDEP GWQS in M-14 Landfill ground water monitoring wells, a Classification Exception Area is not proposed.

8.3 Surface Water Conclusions

During the current reporting period, surface water samples collected at the nearest upstream sampling point (SS-19) from the M-14 Landfill exceeded NJDEP SWQS for arsenic, bromodichloromethane, and lead. Surface water samples collected at the nearest downstream sampling point (SS-09) from the M-14 Landfill exceeded NJDEP SWQS for arsenic and lead. As discussed in depth in Section 6.0, metal detections in general, and lead specifically, are the direct result of acid leaching of suspended solids in water samples. Thus, metals are not considered COCs at the M-14 Landfill.

Bromodichloromethane was detected during the June 2010 stream sampling event at stream sampling point SS-19. This is considered an isolated detection and is the first time bromodichloromethane has been detected at SS-09 since surface water sampling began at Husky Brook in 3rd Quarter 1996. Thus, bromodichloromethane is not considered a COC.

8.4 Soil Conclusions

SVOCs and metals were detected in M-14 Landfill surface soil samples at concentrations exceeding the NJDEP's NRDCSRS. Metals are naturally-occurring within Fort Monmouth soils, as detailed in Section 6.0 and Appendix H. VOCs and PCBs were detected at concentrations in compliance with the NJDEP NRDCSRS. Given the inactive and undisturbed state of the landfill, the lack of groundwater use at or hydraulically downgradient of the M-14 Landfill, and low COC

concentrations in shallow surface soils, No Further Action is recommended for the near-surface soils at the M-14 Landfill.

To address M-14 Landfill near-surface soil samples that do not meet NJDEP soil remediation standards, the Army plans to prepare a Remedial Action Selection Report (RASR)/Feasibility Study (FS) that will include a final closure plan for the M-14 Landfill.

8.5 Sediment Conclusions

With the exception of one anomalous duplicate sample detection of the PCB Arcolor 1254, no PCBs were detected in any of the 25 sediment samples collected from Husky Brook as detailed in Versar's October 2003 *RIR and Sediment Quality Evaluation for the M-14 Landfill*. Based on NJDEP's guidance criteria, PCBs are not impacting sediments in Husky Brook. In addition, no potential exists for long-term, adverse, benthic effects in Husky Brook associated with the M-12 and M-14 Landfills. NFA is warranted for Husky Brook sediments adjacent to the M-12 and M-14 Landfills.

8.6 Recommendations

The following actions are planned:

- Prepare a Remedial Action Selection Report (RASR)/Feasibility Study (FS) that will include a final closure plan for the M-12 Landfill.
- Continue quarterly ground water and surface water sampling until closure of Fort Monmouth in September 2011. At that time, future sampling will be evaluated and discussed with NJDEP.

8.7 RA Schedule

The table/Gant Chart provided in Appendix J is a schedule summary for remedial activities at the M-14 Landfill from the PA phase through the end of the current reporting period and estimated into the future. This table/Gantt chart includes actual costs and schedules to date and estimated/anticipated costs and schedule projected for future activities.

- ~~*The Army will prepare a Remedial Action Selection Report (RASR)/Feasibility Study (FS) which will include a final closure plan for the M-14 Landfill.*~~
- ~~*No further action is proposed for ground water at the M-14 Landfill. Since no COCs exceed NJDEP GWQS in site ground water monitoring wells, a Classification Exception Area is not*~~

~~*required.*~~

- ~~*Discontinue the ground water sampling program at the M-14 Landfill since no COCs exceed NJDEP GWQS in site ground water monitoring wells.*~~
- ~~*No further action is proposed for Husky Brook surface water at the M-14 Landfill.*~~
- ~~*No further action is proposed for M-14 Landfill near-surface soils.*~~
- ~~*No further action is proposed for Husky Brook sediments at the M-14 Landfill.*~~

~~*8.5 Sampling Program*~~

~~*The following tables provide a summary of the recommended future ground water and surface water sampling program at the M-14 Landfill.*~~

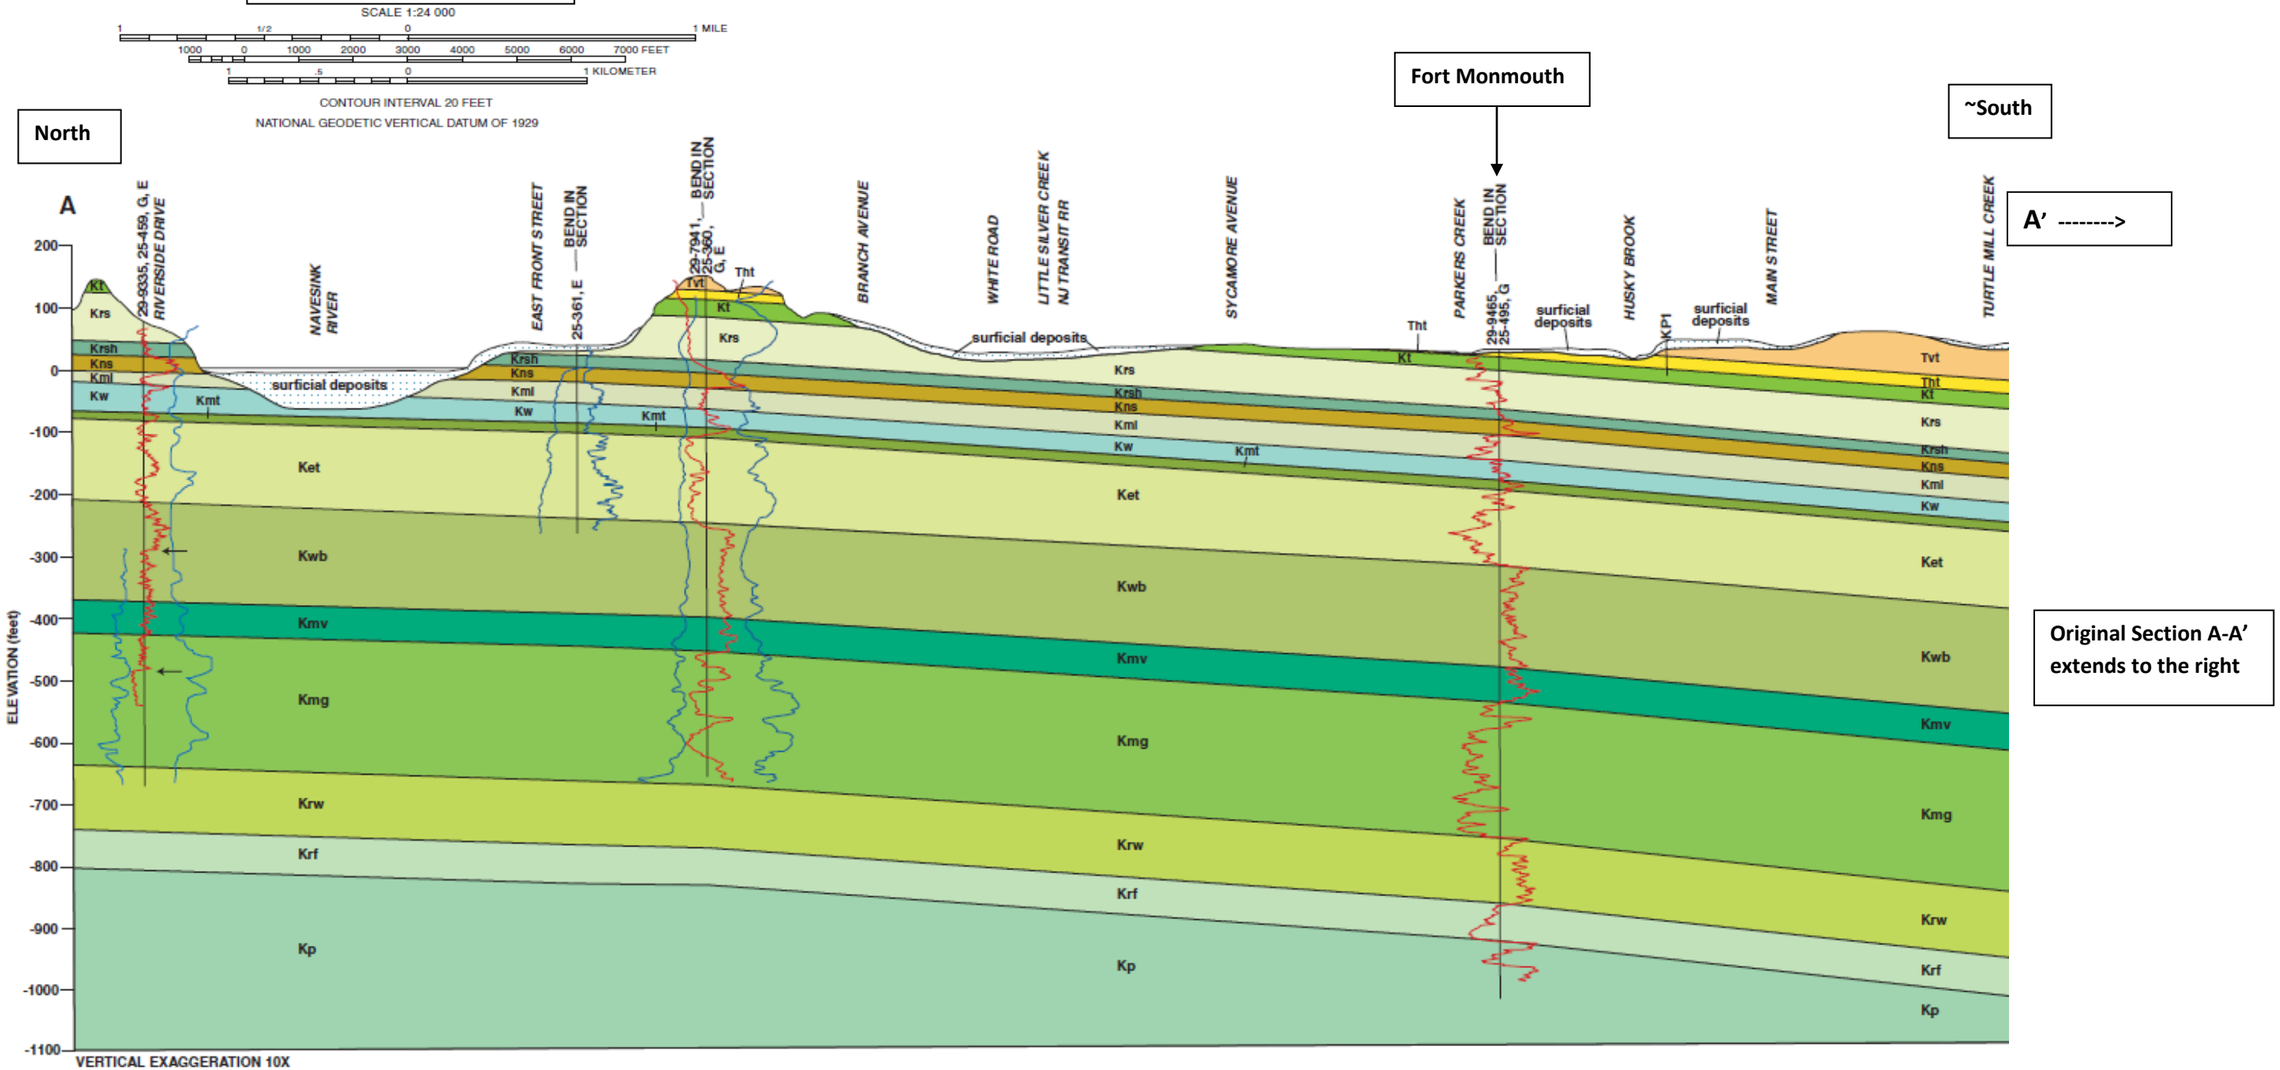
BEDROCK GEOLOGY OF THE LONG BRANCH QUADRANGLE MONMOUTH COUNTY, NEW JERSEY

by
Scott D. Stanford and Peter J. Sugarman
2010

Excerpt of Cross-Section A-A'



Original Section A-A' extends to the right

Description of Geologic Units Shown on Cross-Section A-A'

Tvt VINCENTOWN FORMATION—Glauconitic (5-20%) silty medium-to-coarse quartz sand, some fine-to-medium sand, some very coarse sand to very fine pebbles; yellow, reddish-yellow, olive-yellow, olive-brown; unstratified to weakly horizontally stratified. Coarse sands are locally iron-cemented into beds and masses as much as 10 feet thick. Lowermost 10-20 feet of the formation is silty fine-to-medium sand, with more glauconite than upsection. Total thickness of formation is 180 feet. Late Paleocene in age, based on foraminifera (Olsson and Wise, 1987; Miller and others, 2006) and calcareous nannofossils (Sugarman and others, 1991). Unconformably overlies the Hornerstown Formation.

Tht HORNERSTOWN FORMATION—Glauconite (>50%) clay and silty clay; olive, dark green, black where unweathered, olive-brown with brown to reddish-brown mottles where weathered; unstratified. Glauconite occurs primarily in soft grains of fine-to-medium sand size. Thickness is 25 to 30 feet. Early Paleocene in age, based on foraminifera (Olsson and others, 1997; Landman and others, 2004; Miller and others, 2006) and calcareous nannofossils (Sugarman and others, 1991; Miller and others, 2006). Unconformably overlies the Tinton Formation.

Kt TINTON FORMATION—Glauconitic (5-30%) silty medium-to-coarse and fine-to-medium quartz sand; reddish-brown, reddish-yellow, yellowish-brown where weathered, grayish-brown, brown, olive-brown where unweathered; unstratified to weakly horizontally stratified. Commonly iron-cemented into beds and masses as much as 15 feet thick. Uppermost 4-6 feet, just below contact with Hornerstown Formation, is a brown to olive-gray glauconitic clayey-silty fine sand to fine-sandy silt-clay ("New Egypt Formation" of Landman and others, 2004). Total thickness of Tinton is 30 to 40 feet. Late Cretaceous (late Maestrichtian) in age based on foraminifera, nannofossils, and ammonites (Landman and others, 2004) and strontium-isotope ratios (Sugarman and others, 1995). Overlies the Shrewsbury Member of the Red Bank Formation. Contact with Shrewsbury is not exposed in the Long Branch quadrangle. It is gradational over several feet in the Sandy Hook quadrangle, north of the Long Branch quadrangle (Minard, 1969), but may be unconformable in the Marlboro quadrangle, west of the Long Branch quadrangle (Sugarman and Owens, 1996).

Krs RED BANK FORMATION, SHREWSBURY MEMBER—Fine-to-medium quartz sand, minor medium-to-coarse sand, slightly silty, glauconitic (<5%), and micaceous; reddish-yellow, yellow where weathered, light gray and gray where unweathered; unstratified to weakly horizontally bedded; locally iron-cemented. As much as 100 feet thick. Late Cretaceous (late Maestrichtian) in age based on fossils in the underlying Sandy Hook Member; the Shrewsbury Member is unfossiliferous. Grades downward within 2-3 feet to the Red Bank Formation, Sandy Hook Member. On geophysical well logs, transition to Sandy Hook Member is marked by increased gamma-ray intensity and decreased resistance.

Krsh RED BANK FORMATION, SANDY HOOK MEMBER—Fine-sandy clayey silt, micaceous, slightly glauconitic (<5%); brown to yellowish-brown where weathered, dark gray, olive-gray where unweathered; unstratified. Calcareous brachiopod, pelecypod, and gastropod fossils are common. As much as 20 feet thick. Late Cretaceous (late Maestrichtian) in age based on calcareous nannofossils (Sugarman and Owens, 1996), foraminifera (Olsson, 1964; Olsson and Wise, 1987; Owens and others, 1977), and strontium-isotope ratios (Sugarman and others, 1995). Grades downward within 2-3 feet into the Navesink Formation. On geophysical well logs, transition to Navesink is marked by increased gamma-ray intensity and slightly decreased resistance.

Kns NAVESINK FORMATION—Glauconitic (20-50%) clayey-silty fine-to-medium quartz sand to fine-sandy clayey silt; dark gray, gray, grayish-brown, olive-gray where unweathered, brown to yellowish-brown where weathered; unstratified. Glauconite occurs chiefly in soft grains of fine-to-medium sand size. Calcareous brachiopod, pelecypod, and gastropod fossils are common. Late Cretaceous (late Maestrichtian) in age based on calcareous nannofossils and foraminifera (Olsson, 1964; Miller and others, 2006), macrofossils (Sohl, 1977), and strontium-isotope ratios (Sugarman and others, 1995). Unconformably overlies the Mount Laurel Formation. Contact with Mount Laurel is commonly marked by a sharp peak in gamma-ray intensity on geophysical well logs, with reduced intensity in the Mount Laurel.

Description of Geologic Units Shown on Cross-Section A-A' (cont.)

Kml MOUNT LAUREL FORMATION—Glauconitic (3-15%) fine-to-medium quartz sand, minor medium-to-coarse sand, with thin interbeds of clay and silt; yellowish-brown where weathered, olive-gray to olive-brown where unweathered. Sand is unstratified to horizontally bedded to cross-bedded. As much as 50 feet thick in the southern part of the quadrangle; thins to 20 feet to the north. In subsurface only, covered by surficial deposits in the Navesink River estuary and by overlying Coastal Plain formations elsewhere. Late Cretaceous (late Campanian) in age, based on calcareous nannofossils and strontium-isotope ratios (Sugarman and others, 1991; Miller and others, 2006). Grades downward into the Wenonah Formation. On geophysical well logs, transition to Wenonah is generally marked by slightly decreased resistance and increased gamma-ray intensity.

Kw WENONAH FORMATION—Silty fine-to-very-fine quartz sand to fine-sandy clayey silt, micaceous, slightly glauconitic (<5%); yellow, very pale brown where weathered, gray to pale-olive where unweathered; unstratified. As much as 40 feet thick. In subsurface only, covered by surficial deposits in the Navesink River estuary and by overlying Coastal Plain formations elsewhere. Late Cretaceous (late Campanian) in age based on pollen (Wolfe, 1976) and ammonites (Kennedy and Cobban, 1994). Grades downward into the Marshalltown Formation. On geophysical well logs, transition to Marshalltown is marked by increased gamma-ray intensity.

Kmt MARSHALLTOWN FORMATION—Glauconitic (20-50%), slightly micaceous, silty-clayey fine-to-medium quartz sand, to fine-sandy clayey silt; olive-gray to olive-brown; unstratified. Thickness is 15 to 20 feet. In subsurface only. Late Cretaceous (middle Campanian) in age based on calcareous nannofossils, foraminifera, mollusks, and strontium-isotope ratios (Sugarman and others, 1995). Unconformably overlies the Englishtown Formation. On geophysical well logs, contact with Englishtown is marked by decreased gamma-ray intensity and slightly increased resistance.

Ket ENGLISHTOWN FORMATION—Fine-to-medium quartz sand, minor medium-to-coarse sand, with thin interbeds of clay and silt; micaceous and lignitic, with a trace (<1%) of glauconite; white and light gray where weathered, dark gray where unweathered. Sand is unstratified to horizontally bedded to cross-bedded. In subsurface only. As much as 140 feet thick in the eastern part of the quadrangle, thins to 110 feet thick in the west. In the Asbury Park quadrangle to the south of the Long Branch quadrangle, and farther southwest in northern Ocean County, the Englishtown is divided into an upper and lower member based on the presence of a clay-silt facies in the middle of the formation that is distinctive on gamma-ray logs (Nichols, 1977; Sugarman and Owens, 1994; Miller and others, 2006). This facies is not well marked on gamma-ray logs in the Long Branch quadrangle (wells 29-9335, 29-7941, 29-9465, 29-6173, 29-23948, and 29-48307) and so the members are not mapped here. Late Cretaceous (middle to late Campanian) in age, based on pollen (Wolfe, 1976), ostracodes (Gohn, 1992), calcareous nannofossils, and strontium-isotope ratios (Miller and others, 2006). Grades downward into the Woodbury Formation. On geophysical well logs, transition to Woodbury is marked by increased gamma-ray intensity and decreased resistance.

Kwb WOODBURY FORMATION—Clay, silty clay, with minor thin beds of very fine quartz sand, slightly micaceous and lignitic; dark gray and black where unweathered, yellowish-brown to brown where weathered; unstratified. In subsurface only. As much as 240 feet thick in the eastern part of the quadrangle, thins to 160 feet thick in the central and western parts of the quadrangle. Late Cretaceous (early to middle Campanian) based on pollen (Wolfe, 1976), ostracodes (Gohn, 1992), and calcareous nannofossils (Miller and others, 2006). Grades downward into the Merchantville Formation. On geophysical well logs, transition to the Merchantville is marked by slightly increased gamma-ray intensity.

Description of Geologic Units Shown on Cross-Section A-A' (cont.)

Kmv MERCHANTVILLE FORMATION—Glauconitic (20-50%) clayey silt to sandy clayey silt, slightly micaceous; olive, dark gray, black where unweathered, olive-brown to yellowish-brown where weathered; unstratified. Thickness is 40 to 60 feet. In subsurface only. Late Cretaceous (early Campanian to Santonian) in age based on ammonites (Owens and others, 1977) and calcareous nannofossils (Miller and others, 2006). The Cheesequake Formation, a glauconitic clayey silt underlying the Merchantville, is mapped in outcrop in northern Monmouth and eastern Middlesex counties (Sugarman and Owens, 1996; Sugarman and others, 2005; Stanford and Sugarman, 2008) and in the subsurface both west and south of the Long Branch quadrangle (Sugarman and Owens, 1994, 1996). Because it is lithically similar to the Merchantville and cannot be easily distinguished from it on geophysical logs, it is not mapped separately here. If present, it is included here within the Merchantville, or uppermost Magothy Formation.

Kmg MAGOTHY FORMATION—Fine-to-medium quartz sand, some very-fine-to-fine sand and minor medium-to-coarse sand, micaceous, lignitic, and pyrite-bearing in places, with thin interbeds of silt and clay; white to yellow where weathered, light gray to gray where unweathered. Sand is cross-bedded to laminated. As much as 220 feet thick. In subsurface only. Late Cretaceous (Turonian-Santonian) in age, based on pollen (Christopher, 1979, 1982; Miller and others, 2006). Unconformably overlies the Raritan Formation, Woodbridge Clay member. On geophysical well logs, contact with the Woodbridge is marked by increased gamma-ray intensity.

In its outcrop area in eastern Middlesex County the Magothy is divided into 5 members. From bottom to top they include: South Amboy Fire Clay, Old Bridge Sand, Amboy Stoneware Clay, Morgan beds, and Cliffwood beds (Sugarman and others, 2005). The Old Bridge is a thick sand, the other members are interbedded clay-silt and fine sand. These members may extend downdip in the subsurface (Miller and others, 2006). Geophysical well logs in the Long Branch quadrangle (wells 29-21612, 29-23948, 29-21510, 29-9335, 29-7941, 29-9465, and 29-6173) show generally higher gamma-ray intensity and lower resistivity in the uppermost 50 feet of the formation, and again in the lowermost 30-40 feet, than in the middle 100-120 feet. The upper fine-grained beds may correspond to the Amboy Stoneware Clay and Morgan and Cliffwood beds, and the lower fine-grained beds may correspond to the South Amboy Fire Clay. The middle sand may correspond to the Old Bridge Sand.

Krw RARITAN FORMATION, WOODBRIDGE CLAY MEMBER—Clay and silt, micaceous, lignitic, and pyrite-bearing; gray and black where unweathered, white to brown where weathered; with minor thin interbeds and laminas of white, yellow, and light gray very-fine-to-fine quartz sand. As much as 110 feet thick. In subsurface only, penetrated by wells 29-9465 and 29-1921. The driller's log for well 29-2366 in Eatontown reports "weathered bedrock", with no further information, beneath the Magothy Formation, at a depth of 875-891 feet. This depth is anomalously shallow for the basement surface, suggesting that the material may be weathered clay of either the Woodbridge or South Amboy Fire Clay member of the Magothy. The Woodbridge is Late Cretaceous (late Cenomanian) in age based on pollen (Christopher, 1979) and ammonites (Cobban and Kennedy, 1990). Grades downward into the Raritan Formation, Farrington Sand member. Transition to the Farrington is marked by decreased gamma-ray intensity on geophysical well logs.

Krf RARITAN FORMATION, FARRINGTON SAND MEMBER—Fine-to-coarse quartz sand, some coarse-to-very-coarse sand, minor beds of clay and silt; white and yellow where weathered, gray where unweathered. Sands are horizontally bedded to cross-bedded. As much as 60 feet thick. In subsurface only, penetrated in well 29-9465. Late Cretaceous (Cenomanian) in age based on pollen (Christopher, 1979). Unconformably overlies the Potomac Formation. Contact with Potomac is marked by increased gamma-ray intensity on geophysical well logs.

Description of Geologic Units Shown on Cross-Section A-A' (cont.)

Kp POTOMAC FORMATION—Fine-to-medium quartz sand, some coarse-to-very-coarse sand, with beds of clay and silt; white, red, yellow where weathered, gray where unweathered. Sands are horizontally bedded to cross-bedded, clays are in beds as much as 8 feet thick. More than 90 feet thick, full thickness not penetrated in the Long Branch quadrangle. In subsurface only, partially penetrated in well 29-9465. Late Cretaceous (Albian-Cenomanian) based on pollen (Sugarman and Owens, 1996; Miller and others, 2006), which indicates that the Potomac in this area corresponds to the Potomac Formation, unit 3, of Doyle and Robbins (1977).

LANDFILL DELINEATION PROJECT LOG

SUBSURFACE EVALUATOR: Harold Hornung

LANDFILL: **M 14** EXCAVATION ID: **5**

EXCAVATION DESCRIPTION

LANDFILL MATERIAL PRESENT: YES **X** NO
DESCRIBE**: Brick and concrete found 4' BGS.**

NATURAL MATERIAL PRESENT: YES NO **X**
DESCRIBE**:**

GPS POSITIONS
BEGINNING OF EXCAVATION
Y COORDINATE (NORTHING**): 539711.07** X COORDINATE (EASTING):**621079.11**

END OF EXCAVATION
Y COORDINATE (NORTHING):**539707.35** X COORDINATE (EASTING):**621068.92**

EXCAVATION PHOTOGRAPHED: YES **X** NO

PHOTOGRAPH INDENTIFICATION: **7 14:23**

NOTES**: Did not step out 10' to North because it is assumed that the same concrete and brick will be found that was observed in excavations M14-3 and M14-4.**
Map color code = red

SUBSURFACE EVALUATOR SIGNATURE:_____

LANDFILL DELINEATION PROJECT LOG

SUBSURFACE EVALUATOR: Harold Hornung
EQUIPMENT OPERATOR: **Ed Crawley**
DATE: **09/30/08**
LANDFILL: **M 14** EXCAVATION ID: **6**

EXCAVATION DESCRIPTION

LANDFILL MATERIAL PRESENT: YES **X** NO
DESCRIBE**: 0-6.5' BGS soil. At 6.5' BGS found leather shoe parts, china plates with gold trim, bottles, copper wire, and ash.**

NATURAL MATERIAL PRESENT: YES NO **X**
DESCRIBE**:**

GPS POSITIONS
BEGINNING OF EXCAVATION
Y COORDINATE (NORTHING**): 539687.81** X COORDINATE (EASTING):**621012.76**

END OF EXCAVATION
Y COORDINATE (NORTHING):**539684.56** X COORDINATE (EASTING):**621001.38**

EXCAVATION PHOTOGRAPHED: YES **X** NO

PHOTOGRAPH INDENTIFICATION: **8, 9, 10 14:57, 14:58, 14:58**

NOTES**: Move 25 feet North and 7 feet East to delineate because basketball court and utilities are in the way of it at 10' (M14-6A). Noticed bubbling in the GW in the excavation VOC reading = 0, LEL =3, CO=0, 0_2 = 20.9. H_2S=0. All LEL readings have been 0 to this point. This appears to be actual landfill material and not just fill.**
Map color code = red

Compounds exceeding NJDEP soil cleanup criteria are noted by bold numbers.
bgs - Below Ground Surface
J - Indicates that the concentration value was estimated due to detection at or near the detection limits
C- Pesticide identification was confirmed by GC/MS
P - The percent difference between the results from two GC columns is greater than 25%,the lower of the two values is reported
B - Compound was observed in the sample and associated laboratory blank.
D - surrogate or matrix spike recoveries were not obtained because the extract was diluted for analysis
ND - Indicates that the compound was not detected at or below the quantification limits
NLE - No Level Established
Note:MDL's for metal analysis is actually the highest detection limit with potassium given as a range due to high variability
[1] Monmouth County maximum background concentration.
[2] NJDEP criteria are referenced in the Site Remediation News, Winter 1995.

addition, compounds that exceed the SCC are subsequently compared to the impact to groundwater SCC because there were no monitor wells installed at the site.

SVOCs

Three SVOCs were detected above laboratory quantitation limits in site soils, but were well below NJDEP SCC. In addition, all other detected compounds with established SCC were found in concentrations below their respective criteria. The detected compounds did not exceed the impact to groundwater SCC.

Pesticides/PCBs

Two pesticides (4,4'-DDE and 4,4'-DDT) were detected in concentrations above NJDEP SCC and background in SS-01. The concentrations of 4,4'-DDE and 4,4'-DDT were well below the respective impact to groundwater criteria (Figure 4.2-24). Pesticides were not detected above criteria in SS-02. PCBs were not detected in site surface soil samples.

Metals

As indicated in Table 4.2-13, of the 20 metals detected in site soil, 3 (cadmium, lead, and zinc) were found in concentrations exceeding the NJDEP SCC. In addition, these metals were found in concentrations greater than those determined for site-specific and Monmouth County maximum background at the Main Post. Figure 4.2-24 presents the locations of compounds detected above the SCC and the established maximum background concentrations at the Main Post.

4.2.10.5 Recommendations

Two pesticide compounds and three metals, cadmium, zinc, and lead, were detected in surface soil at levels that exceeded NJDEP SCC and maximum background.

DPW has submitted the necessary documentation to Headquarters, Army Materiel Command/Army Environmental Center (HQAMC/AEC) to obtain the proper funding to remediate the site in FY 1996. Depending on funding availability, the affected soil will be excavated and disposed of in accordance with the applicable regulations. The area of contamination encompasses the perimeter of the tank, about 10 feet at the widest point. The depth of contamination is assumed to be 6 inches. Excavation will be performed in conjunction with confirmatory soil sampling to ensure that NJDEP SCC are achieved. It is estimated that 13 yd^3 of soil will be excavated, assuming that soil is excavated to a depth of 6 inches. NJDEP will be requested to send a representative to observe the excavation.

Site M-16

4.2.11 Former Pesticide Storage Building (M-16)

4.2.11.1 Site Location

The former Pesticide Storage Building (M-16) was misidentified as Building 167 in the IA. The building actually used for pesticide storage was Building S-498, which is located on the south-side of Riverside Avenue, north of the marina (Figure 4.2-25). The approximate area of site M-16 is 1,400 ft^2 (0.03 acre).

4.2.11.2 Site History

Building S-498 was built in 1939. According to long-term Fort Monmouth employees, this building was used as a pesticide control shop in the 1940s and 1950s, before this function was moved to Building T-65. Building S-498 is currently used for miscellaneous storage. During the 1993 site visit, workers were bricking in the windows. The front of the building has a tile floor and was most likely used for office space. The back wing of the building has a cement floor with a centrally located floor drain. The southeast corner of the floor has sunk 2 to 3 inches, breaking away from the foundation and creating a crack in the area of the door. The cracks and floor drain could have allowed the release of spilled pesticides. Pesticide mixing reportedly took place inside the building with rinse water dumped in a sink that went to the sanitary sewer.

4.2.11.3 Sampling Effort

Four soil samples were collected from 6 to 12 inches bgs from areas that are not paved south of the building and analyzed for TCL +30 parameters (Figure 4.2-25). Soil samples were collected from two discrete intervals in the monitor well boring and analyzed for TCL +30 parameters and TAL metals. TAL metal analysis was not proposed in the CDAP but samples were collected at SB-01. One monitor well (MW-22) was south of Building S-498. Two rounds of groundwater samples from the monitor well were analyzed for TCL +30 parameters. In addition, an attempt was made to determine whether the floor drain discharges to the sanitary sewer at Building S-498. However, because the original floor in the building was reconstructed as a result of past

flooding problems, the original drainage line was no longer accessible and, consequently, could not be traced from Building S-498 to the sanitary sewer.

4.2.11.4 Hydrogeologic Interpretation

The lithologic log from MW-22 indicates that the lithology consists of a thin (0.4 ft) soil cover with crushed asphalt (to 2 ft bgs) underlain by interbedded green-brown fine-coarse sandy clay and fine-coarse sand with little clay.

Saturation was observed at 1 ft bgs. Monitor well MW-22 was screened in the saturated zone and was completed to a depth of 14.5 ft bgs. The site-specific groundwater flow direction is estimated to be south toward Oceanport Creek (Figure 4.2-26).

4.2.11.5 Soil Sampling Results

One shallow soil boring (SB-01) was installed in the MW-22 borehole to a depth of 6 ft bgs. Soil samples were collected in the borehole from two discrete intervals, i.e., 0 to 2 ft bgs and 2 to 4 ft bgs. In addition, four surface soil samples were collected from the 0 to 0.5 ft bgs interval. Soil samples were sampled for the analytical parameters listed in Table 3.6-1. The analytical results for site soils are listed in Appendix D. Table 4.2-14 compares detected compounds with the NJDEP SCC, and then compares the results to the subsequent site-specific and Monmouth County maximum background levels, where appropriate.

VOCs

VOCs were not detected in site soils.

SVOCs

Three SVOCs were detected slightly above laboratory quantitation limits in site soils. The compounds were detected well below their respective NJDEP SCC. In addition, SVOCs

Compounds exceeding NJDEP cleanup criteria are noted by bold numbers.
J - Indicates that the concentration value was estimated due to detection at or near the detection limits
C- Pesticide identification was confirmed by GC/MS
D - Surrogate or matrix spike recoveries were not obtained because the extract was diluted for analysis.
P - The percent difference between the results from two GC columns is greater than 25%,the lower of the two values is reported
B - Compound was observed in the sample and associated laboratory blank
NA- Not Analyzed - Not Proposed ; NLE - No Levels Established
ND - Indicates that the compound was not detected at or below the quantification limits
ft bgs. - feet below ground surface.
[1] - VOC's/SVOC's were collected from sample interval 6" to 12" bgs; Pesticide/PCB's were collected from sample interval 0.0" to 6" bgs.
Note: Metal analysis was not proposed or analyzed at surface soil locations. Metals analysis was not proposed at SB-01,but was analyzed.
Note: MDL's for metal analysis are actually the highest detection limit with potassium given as a range due to high variability.
[2] Monmouth County maximum background concentration.
[3] NJDEP criteria are referenced in the Site Remediation News, Winter 1995.

detected below laboratory quantitation limits were found in levels well below their respective criteria where established.

Pesticides/PCBs

A total of 10 pesticide compounds were detected above laboratory quantitation limits in site soil. Five pesticides (dieldrin, heptachlor, aldrin, 4,4'-DDE, and 4,4'-DDT) were found in concentrations exceeding the NJDEP SCC. Dieldrin was detected in soil boring SB-01 (0 to 2 ft bgs) and in surface soil samples SS-01 through SS-04. Heptachlor, aldrin, 4,4'-DDE, and 4,4'-DDT were detected at or above criteria in SS-01, SS-02, SS-03, and SS-04. None of the pesticides were detected above their respective impact to groundwater criteria. PCBs were not detected in site soil (Figure 4.2-27).

Metals

As indicated in Table 4.2-14, no metals were detected in concentrations above either the NJDEP SCC or established maximum background concentrations at the Main Post.

4.2.11.6 Groundwater Sampling Results

Monitor well MW-22 was sampled for the analytical parameters listed in Table 3.8-1. The compounds detected in groundwater samples from the individual sampling rounds, with the corresponding sample identifications, are listed in Appendix D. Table 4.2-15 compares the average concentrations of the detected compounds from the February and March sampling rounds with the NJDEP GWQC, and then compares the results to the subsequent site-specific and Monmouth County maximum background concentrations, where appropriate.

VOCs

VOCs were not detected in MW-22 from either sampling round.

Table 4.2-15
Fort Monmouth -Main Post
Summary of Average Concentrations of Detected Compounds in Groundwater
Site M-16

COMPOUND	METHOD DETECTION LIMIT	NJDEP GW QUALITY CRITERIA (µg/L)	MAXIMUM BACKGROUND CONCENTRATION (µg/L)	ANALYTICAL RESULTS (µg/L) SAMPLING DATE		
				MW22A01 2/17/95	MW22A02 3/9/95	MW22A02 (avg)
SVOCs (µg/L)						
bis-(2-Ethylhexyl)phthalate	9.7	30*	5 J	ND	1J	0.5 J

Compounds detected above NJDEP standards are noted by bold numbers.
GW - Ground water
NJDEP groundwater quality criteria consist of the higher number between the PQL or the STANDARD.
*PQL - Practical Quantitation Limit was used as the NJDEP groundwater quality criteria
J - Indicates that the concentration value was estimated due to detection at or near the quantification limits
ND - Indicates that the compound was not detected at or below the quantification limits

SVOCs

SVOCs were not detected above laboratory quantitation limits in MW-22 from either sampling round. The SVOC bis(2-ethylhexyl) phthalate was detected below the laboratory quantitation limit and well below the NJDEP GWQC.

Pesticides/PCBs

Pesticides/PCBs were not detected in MW-22 from either sampling round.

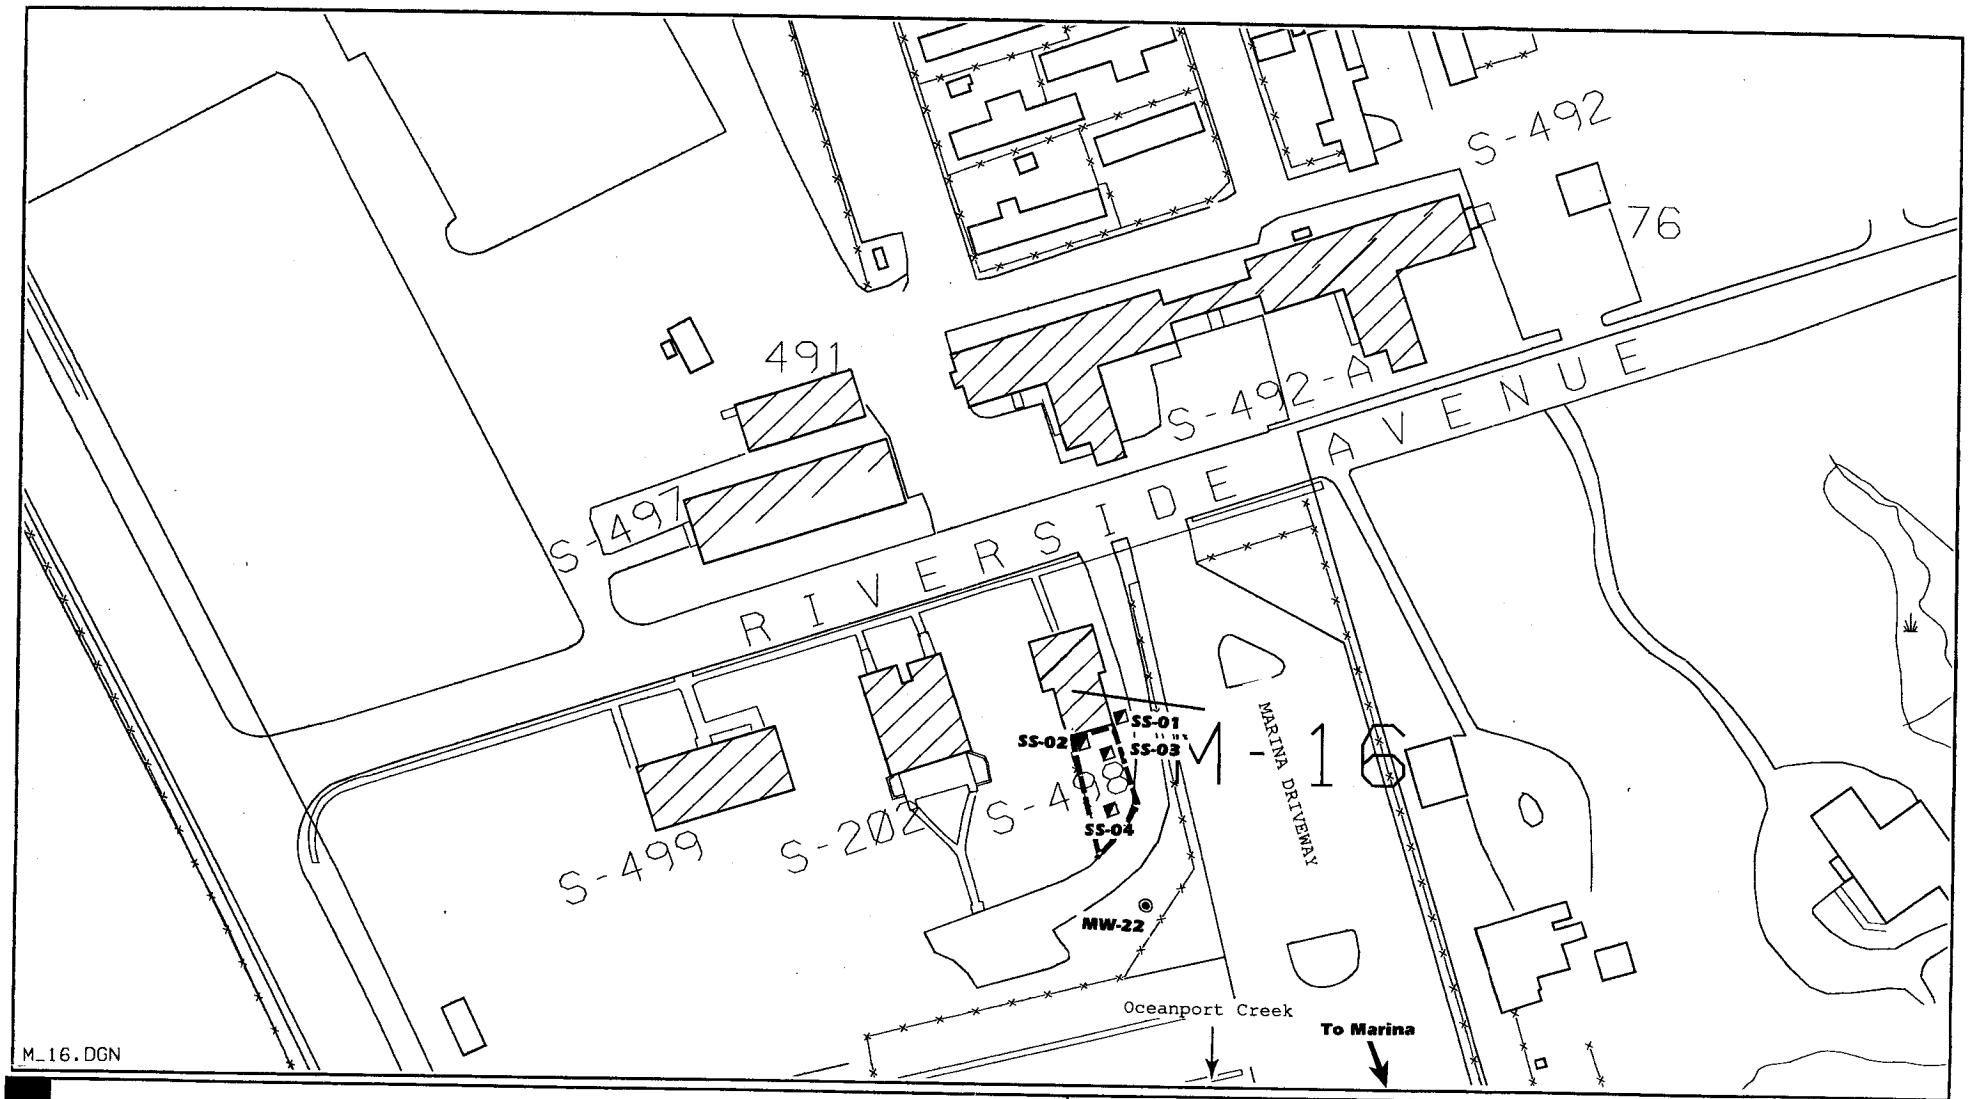
4.2.11.7 Recommendations

Pesticide compounds were detected at four surface soil sampling locations and in one soil boring sample (0 to 2-foot interval) in concentrations above NJDEP criteria and background.

No compounds of concern were detected in the groundwater above NJDEP criteria.

DPW has submitted the necessary documentation to HQAMC/AEC to obtain the proper funding to remediate the site in FY 1996. Depending on funding availability, the affected soil will be excavated and disposed of in accordance with the applicable regulations. The area of contamination is approximately 50 feet by 20 feet. The depth of contamination is assumed to be 12 inches. Excavation will be conducted in conjunction with confirmatory soil sampling to ensure that NJDEP SCC are achieved. It is estimated that 56 yd^3 of soil will be excavated, assuming that soil will be excavated to a depth of 12 inches. NJDEP will be requested to send a representative to observe the excavation.

The site monitor well will be properly abandoned due to the nondetection of compounds of concern in groundwater. The remedial activities proposed will remediate potential source areas of pesticides detected in soil.



Fort Monmouth, Main Post

FIGURE 4.2-27
FORMER PESTICIDE STORAGE BUILDING (M-16)
DISTRIBUTION OF CONTAMINANTS IN SITE SOIL

Site M-18

4.2.12 Former Training Area (M-18)

4.2.12.1 Site Location

The Army Signal School Training Area (M-18) is located in the northern part of the Main Post, between Parkers Creek to the north and Buildings 283, T-294, T-293, S-289, and S-145 to the south (Figure 4.2-28). The approximate area of site M-18 is 177,300 ft^2 (4.1 acres).

4.2.12.2 Site History

The Army Signal School Training Area has been used for military training exercises since 1919. Diesel and gasoline generators used to support these field exercises were reported in the IA to have been used 150 meters from Lafetra Creek, although the location shown in Figure 7 of the IA is closer to Parkers Creek. The IA reports that numerous fuel spills occurred in the generator area. A riot control agent was also used in this area for troop protective mask training for a limited period of time. During the 1993 site inspection, military training area exercises were being conducted in the M-18 area. Part of the area is paved. Based on the presence of concrete at the surface, there is a suspected debris disposal area used for the disposal of building rubble in the area north of Building 289.

4.2.12.3 Sampling Effort

GPR and electromagnetic (EM) surveys were conducted to investigate the extent of debris disposal north of Building 289. Nine soil borings in a grid pattern were drilled in this area (Figure 4.2-28). The original scope of work included the installation of 12 soil borings. However, because of difficult drilling locations in marshy areas, the borings were repositioned and fewer borings were installed. Soil samples were analyzed for VOCs and TPHs and were collected from either 6 to 12 inches or 12 to 18 inches below the bottom of the asphalt (to avoid bias from the asphalt that covers about half of this area) and either from intervals with visible staining or from just above the water table. If staining was observed, samples were collected for SVOC analysis. If staining or high HNu, organic vapor analyzer (OVA), or organic vapor monitor (OVM) readings were recorded, a sample was collected for TCL +30 parameters and

TAL metals. Due to soil staining and elevated PID readings at SB-06, TCL +30 parameters and TAL metals were sampled. No evidence of contamination was present at the other soil sampling locations. Monitor wells were installed in two of the borings (MW-24 and MW-25), and two rounds of groundwater samples were collected for TCL +30 parameters, TAL metals, and TPHs. In addition, two rounds of groundwater samples were collected from previously installed monitor well MW-3.

4.2.12.4 Geophysical Results

The EM survey conducted at site M-18 reveals apparent background conductivities in the range of 25 to 40 mS/m, which are represented by the green to yellow color contour intervals as shown in Figure 4.2-29. These conductivities are indicative of silty soils. High conductivity readings exist toward the north and perimeter of the site (70 + mS/m). This is probably due to marsh deposits and partially to cultural features such as the chainlink fence surrounding the site.

Anomalous conductivity signatures located at 0N to 60S/65E to 95E contain both high conductivity and low conductivity (positive and negative) readings. This may be indicative of buried metallic objects or abrupt changes in subsurface materials.

The in-phase component reveals a strong discrete anomaly located at approximately 0N to 10S/80E to 100E (represented by the blue color contours). This anomaly is adjacent to the quadrature anomalies. Also, discrete in-phase anomalies located within grid coordinates 0N to 60N/170E to 250E are indicative of buried metallic objects (Figure 4.2-30). The strongest of these point source anomalies is located at 15N to 25N/180E to 195E. Other discrete anomalies indicative of buried metallic objects are located at 50N/350E, 30N/360E, and on the east side of the fence at 60N/415E.

The GPR survey at site M-18 revealed anomalous radar signatures (including a hyperbolic diffraction pattern) located at 0N to 10S/100E. Figure 4.2-30A shows this anomaly, which coincides with the EM anomaly in Figure 4.2-30 and may be indicative of an underground storage tank (UST) or UST component (i.e., foundation) at a depth of approximately 5 or 6 ft

bgs. The 100E line traverse on Figure 4.2-30A indicates that the suspected UST is approximately 4 feet in length. Figure 4.2-30A reveals that the three areas contain chaotic reflectors, which are indicative of coarse-grained or disturbed subsoil. The areas, centrally located at grid coordinates 50N/250E, 10N/250E, and 50N/350E, coincide with EM anomalies and may contain buried metallic objects. The radar profiles also reveal low amplitude chaotic reflectors, indicative of coarse-grained soils in the area that encompasses low apparent conductivity at the western portion of the site (green contour interval), as shown in Figure 4.2-29.

Although the geophysical survey results indicated areas that may contain buried ferrous material and fill, these areas are within the suspected boundary of the landfill. Monitor wells and soil borings were appropriately located to evaluate subsurface conditions downgradient and within the landfill boundaries.

4.2.12.5 Hydrogeologic Interpretation

Lithologic logs from SB-01 through SB-07 and MW-24 and MW-25 indicate that the lithology consists of fill intermixed with a poorly sorted gray-olive-brown silty fine-coarse-grained sand with trace amounts of clay. The manmade components of the filled materials observed in the borings consisted of asphalt, wood fragments, and roof shingles.

Saturation was observed in monitor wells MW-24 and MW-25 at approximately 6 ft bgs. Both monitor wells were screened across the water table and were completed to 15 ft bgs. Local groundwater flows toward and discharges into Parkers Creek (Figure 4.2-31), as indicated by water-level measurements from site monitor wells and land surface topography. Monitor wells MW-24 and MW-25 are positioned downgradient of the M-18 area.

4.2.12.6 Soil Sampling Results

A total of nine shallow soil borings (Figure 4.2-32) were completed at selected locations at site M-18 to depths ranging from 2 to 10 ft bgs. Two soil borings (SB-24 and SB-25) were completed at the new monitor wells (MW-24 and MW-25) locations. Locations were selected

for seven of the borings based on the results of the geophysical surveys. Soil samples were collected from two discrete intervals (1 to 1.5 ft bgs and 2 to 10 ft bgs, depending on the depth to water), and based on field observations, were sampled for the analytical parameters listed in Table 3.6-1. The analytical results for soils at specific sampling intervals are listed in Appendix D. Tables 4.2-16 and 4.2-17 compare the detected compounds with the NJDEP SCC, and then compare the results with the subsequent site-specific and Monmouth County maximum background levels, where appropriate. Stained soil was observed below ground surface, but in the 0 to 2-ft bgs sampling interval at boring SB-06. In accordance with the work plan, samples were also taken for BNAs (SVOCs), pesticides/PCBs, and metals analysis at this location.

VOCs

VOCs were not detected above the laboratory quantitation limit in site soils. VOCs detected below quantitation limits were well below their respective criteria (Table 4.2-16).

SVOCs

A total of 13 SVOCs were detected above laboratory quantitation limits in SB-06. Four of the compounds [benzo(a)anthracene, chrysene, benzo(k)fluoranthene, and ideno(1,2,3-cd)pyrene] were detected in concentrations above laboratory quantitation limits and above the NJDEP SCC at SB-06 in the 2- to 5-ft bgs sampling interval. In addition, two compounds [benzo(b)fluoranthene and benzo(a)pyrene], detected below laboratory quantitation limits in SB-06, were also found in concentrations exceeding the NJDEP SCC from the 2- to 5-ft bgs sampling interval. All other detected SVOCs were found in concentrations below the established criteria. All six of the compounds that exceeded the NJDEP criteria also exceeded the site and Monmouth County background. Although the SVOCs were found in concentrations above NJDEP SCC and maximum background in SB-06, the concentrations were well below the impact to groundwater SCC. Monitor wells downgradient of this location did not detect these particular SVOCs. Figure 4.2-32 presents the locations of the compounds detected above the NJDEP SCC and the established maximum background levels at the Main Post.

Compounds exceeding NJDEP cleanup criteria are noted by bold numbers.
ft bgs - Feet below ground surface
NLE - No Level Established
ND - Indicates that the compound was not detected at or below the quantification limits
J - Indicates that the concentration value was estimated due to detection at or near the detection limits
B - Compound was observed in the samples and associated laboratory blank
NA- Not Analyzed
C- Pesticide identification was confirmed by GC/MS
P - The percent difference between the results from two GC columns is greater than 25%,the lower of the two values is reported
U - Compound was not detected at or above the reporting limit.
X - Other specific flags may be required to properly qualify the result.

[1] Monmouth County maximum background concentration.

[2] NJDEP criteria are referenced in the Site Remediation News, Winter 1995.

Pesticides/PCBs

Five pesticides were detected in concentrations above laboratory quantitation limits in SB-06 from the 2- to 5-ft bgs sampling interval. However, all pesticide compounds were detected below the NJDEP SCC. PCBs were analyzed for but were not detected in any of the boring locations.

Metals

As indicated in Table 4.2-17, metals detected in SB-06 were found in concentrations below the NJDEP SCC.

Total Petroleum Hydrocarbons (TPHs)

TPH concentrations were detected above laboratory quantitation limits in one or both sampling intervals in all but soil boring SB-04 in concentrations ranging from 29.9 milligrams per kilogram (mg/kg) to 6,330 mg/kg.

4.2.12.7 Groundwater Sampling Results

Monitor wells at site M-18 were sampled for the analytical parameters listed in Table 3.8-1. The compounds detected in groundwater samples from the individual sampling rounds, with the corresponding sample identifications, are listed in Appendix D. The existing monitor well, MW-3, was sampled in May 1995. Table 4.2-18 compares the average concentrations from the February and March sampling rounds with the NJDEP GWQC, and then compares the results to the subsequent site-specific and Monmouth County maximum background, where appropriate.

VOCs

Acetone was the only VOC detected in site groundwater samples. Acetone was detected in concentrations below the NJDEP GWQC in groundwater samples collected from MW-24 and

Compounds exceding NJDEP groundwater quality criteria are noted by bold numbers.
NJDEP groundwater quality criteria consist of the higher number between the PQL or STANDARD
*PQL - Practical Quantitation Limit -was used as the NJDEP groundwater quality criteria
NLE - No Level Established
ND - Indicates that the compound was not detected at noted quantification limit
NA - Not analyzed
J - Indicates that the concentration value was estimated due to detection at or near the quantification limits
P - The percent difference between the results from two GC columns is greater than 25%, the lower of the two values is reported.
[1] - Monmouth County maximum background concentration.

MW-25. The source of the acetone is not known, however, acetone is a common laboratory contaminant.

SVOCs

One SVOC (4-methylphenol) was detected in MW-24 below the laboratory quantitation limit. SVOCs were not detected in MW-25 or MW-3.

Pesticides/PCBs

One pesticide (4,4'-DDD) was detected in a concentration that slightly exceeds the NJDEP GWQC in MW-24. 4,4'-DDD was detected in concentrations above the criteria in MW-24 from both sampling rounds. PCB compounds were not detected in site monitor wells from either sampling round (Figure 4.2-32).

Metals

As indicated in Table 4.2-18, of the 19 metals detected in site groundwater, only 6 (aluminum, arsenic, iron, manganese, sodium, and lead) were found in concentrations exceeding the NJDEP GWQC. In addition, manganese in MW-24 and MW-25, lead in MW-24, and sodium in MW-25 were found in concentrations greater than those determined for site-specific and Monmouth County maximum background at the Main Post. Lead was not detected in the filtered sample. However, aluminum and arsenic were found in concentrations below both maximum background levels where established. Although iron was detected in concentrations greater than the regional maximum background, iron was detected well below the site-specific background levels in the Main Post and is not a compound of concern. Sodium in MW-3 was found in a concentration greater than the site-specific background, but was well below the Monmouth County level. The elevated sodium levels in MW-25 may be caused by saline water intrusion from the Parkers Creek estuary. Sodium is not a compound of concern (Figure 4.2-32). As discussed in Subsection 4.1, groundwater flowing through glauconitic formations contains abundant

manganese. In addition, manganese is a common metal found in tidally influenced environments. Therefore, manganese is not identified as a compound of concern.

TPHs

TPH concentrations were detected just above the laboratory quantitation limit in MW-24 and MW-25 from both the February and March sampling rounds.

4.2.12.8 Recommendations

The geophysical surveys identified several anomalies indicative of buried waste and fill material within the suspected boundaries of the site M-18 area. One anomaly was indicative of a UST or storage tank component. The geophysical results indicate that soil borings and monitor wells were appropriately located to evaluate subsurface conditions downgradient and within landfill boundaries.

The soil sampling results indicated that six SVOCs were detected at SB-06 in concentrations that exceeded the NJDEP criteria and established background concentrations.

The groundwater sampling results indicate that 4,4-DDD was detected at a concentration just above the NJDEP GWQC in one well (MW-24) from both sampling rounds. Lead was detected in one location above NJDEP GWQC and background. TPH concentrations were also detected just above laboratory quantitation limits in MW-24 and MW-25 in both sampling rounds.

Trenching will be performed at the suspected UST or UST component location to confirm the geophysical results and to excavate if necessary. A PID will be used to conduct field screening during the excavation. The excavation will be performed in conjunction with confirmatory sampling, in accordance with the *Technical Requirements for Site Remediation* (NJDEP, 1993), if a UST is encountered to ensure that NJDEP SCC are achieved. NJDEP will be requested to send a representative to observe the excavation.

Additionally, soil at soil boring SB-06 will be excavated. If it is determined that the suspected UST is the source of contamination at SB-06, this location will be remediated in conjunction with the UST. Confirmatory sampling will also be conducted.

DPW proposes that a long-term groundwater monitoring program be developed and implemented for the site. Aqueous samples would be collected and analyzed on a quarterly basis to further evaluate water quality conditions at the site. Groundwater samples would be collected from existing monitor wells. Compounds of concern identified in the first two rounds of sampling would be targeted for the monitoring program.

FORMER TRAINING AREA (M-18)
DISTRIBUTION OF CONTAMINANTS IN
SITE SOIL AND GROUNDWATER

Site AOC-3

4.2.13 Former Main Post Sanitary Treatment Plant (AOC-3)

4.2.13.1 Site Location

The former Sanitary Treatment Plant (STP, AOC-3) was located on Parkers Creek north of Sherrill Avenue, between Buildings S-292 to the east and S-697 to the west (Figure 4.2-33). The approximate area of site AOC-3 is 96,000 ft^2 (2.2 acres).

4.2.13.2 Site History

This site was identified by the NJDEP as an area of concern (AOC) in the 8 June 1990 letter. The Main Post STP was built in 1941 to handle 700,000 gallons of sewage per day. As described in the IA, this STP consisted of a bar screen and grit chamber, comminutor, primary and secondary settling tanks, a mixing and aeration tank, and a baffled contact chlorination tank. Effluent from the STP was discharged to Parkers Creek. Sludge was treated in a three-stage anaerobic digester and discharged to underdrained sandbeds for drying. According to the IA and DEH employees, sludge was transported to the Charles Wood golf course and to landfills. This STP was closed on 3 September 1975 when the Main Post sewer system was connected to the Northeast Monmouth County Regional Sewerage Authority (NMCRSA) system. In 1981, all sludges and supernatant liquids were removed from the STP and the facility was cleaned and disinfected. The removal contractor was Modern Transportation Co. of Kearny, New Jersey. The physical facility was demolished in 1983. At present, this area is flat and grass covered.

4.2.13.3 Sampling Effort

Sediments from one location in the Parkers Creek outfall area were analyzed for TCL +30 parameters, TAL metals, and cyanide. Two soil borings were completed in the area of the former sludge-drying beds to identify the original land surface and collect soil samples from an interval just below the original surface for TCL +30 parameters, TAL metals, and cyanide (Figure 4.2-33).

4.2.13.4 Soil Sampling Results

Borings were drilled to depths of 12 ft bgs (depth where saturation was encountered). Samples were collected from one sampling interval (6 to 9.5 ft bgs) and were analyzed for the parameters listed in Table 3.6-1. The analytical results for site soils at specific sampling intervals, with the corresponding sample identifications, are listed in Appendix D. Table 4.2-19 compares the compounds detected in site soils with the NJDEP Residential Direct Contact SCC, and then compares the results to the subsequent site-specific and Monmouth County maximum background concentrations, where appropriate. In addition, compounds were also compared to the impact to groundwater SCC because no monitor wells were installed at the site.

VOCs

VOCs were not detected in site soils from either boring location.

SVOCs

SVOCs were not detected above laboratory quantitation limits in site soils. SVOCs detected below laboratory quantitation limits were found in concentrations well below their respective criteria.

Pesticides/PCBs

Of the six pesticides detected in site soil, none were detected above the NJDEP SCC or the impact to groundwater SCC (Table 4.2-19).

One PCB (Aroclor-1248) was detected in SB-02 above the laboratory quantitation limit. However, Aroclor-1248 was found in a concentration below both the NJDEP residential direct contact and impact to groundwater SCC.

Compounds exceeding NJDEP soil cleanup criteria are noted by bold numbers.
NLE - No Level Established
ND - Indicates that the compound was not detected at or below the quantification limits
J - Indicates that the concentration value was estimated due to detection at or near the detection limits
P - The percent difference between the results from two GC columns is greater than 25%,the lower of the two values is reported
D - Surrogate or matrix spike recoveries were not obtained because the extract was diluted for analysis
ft bgs. - feet below ground surface.
Note: MDL's for metal analysis is actually the highest detection limit with potassium given as a range due to high variability.

[1] Monmouth County maximum background concentration.

[2] NJDEP criteria are referenced in the Site Remediation News, Winter 1995.

Metals

As indicated in Table 4.2-19 all of the metals detected in site soil were found in concentrations below the NJDEP SCC.

Cyanide

Cyanide was not detected in site soils from either soil boring.

4.2.13.5 Sediment Sampling Results

Sample location M8SD-1 appears to be tidally influenced, and based on conductivity results and field observations, was determined to be saltwater.

One sediment sample, M8SD-1, was collected at AOC-3 (Figure 4.2-33). Table 4.2-20 presents a comparison of detected sediment concentrations at sampling location M8SD-1 to marine/ estuarine sediment criteria (Long et al., 1995), and maximum detected background concentrations.

VOCs

2-Butanone was the only VOC detected above the laboratory quantitation limit in a site sediment sample. 2-Butanone is a common laboratory contaminant.

SVOCs

Two SVOCs were detected below the laboratory quantitation limit in site sediment from location M8SD1.

Pesticides/PCBs

Pesticides/PCBs were analyzed for but were not detected in the site sediment sample.

Compounds detected above NJDEP Sediment Guidance are noted by bold numbers.

[a] - Value from Long et al. (1995).

ND - Compound was not detected at or above the quantification limit.

NLE - No Level Established

B - Compound was found in the sample and associated laboratory blank

J - Concentration was estimated due to detection at or below the quantification limit

Metals

As indicated in Table 4.2-20, of the 18 metals detected above laboratory quantitation limits, only one (arsenic) was found in a concentration slightly exceeding the established criteria. However, the concentration of arsenic was found at a level below the maximum detected background concentration.

4.2.13.6 Recommendations

The results of the soil and sediment sampling indicated that compounds of concern were not detected above the NJDEP criteria and established background concentrations.

No further action will be taken.

FORMER SANITARY TREATMENT PLANT (AOC-3)
SOIL AND SEDIMENT SAMPLING LOCATIONS

Former Sanitary Treatment Plant (STP)

Former Sanitary Treatment Plant (STP)

4.2.14 Pre-1941 Sanitary Treatment Plant (STP)

4.2.14.1 Site Location

The pre-1941 STP for the Main Post was located on Parkers Creek in an area north of Allen Avenue in approximately the same location as current Building 259 (Figure 4.2-34). The approximate area of the STP is 130,000 ft^2 (2.9 acres).

4.2.14.2 Site History

This STP is shown on a 1935 Fort Monmouth map. The date of construction and period of operation are unknown, although the STP presumably operated until the Main Post STP (AOC-3) came on line in 1941.

4.2.14.3 Sampling Effort

The former STP is presented in Figure 4.2-34. Sediment coring was conducted at the former outfall and a sample was collected for TAL metals analysis.

4.2.14.4 Sediment Sample Results

Sediment at the STP was determined to be saltwater based on conductivity results and field observations. Therefore, detected concentrations of contaminants in the STP sediment were compared to marine/estuarine biological effects levels (Long et al., 1995) (Table 4.2-21).

One sediment sample, STPSD-1, was collected at the former STP (Figure 4.2-34).

Metals

As indicated in Table 4.2-21, of the 21 metals detected above laboratory quantitation limits, nine (arsenic, cadmium, chromium, copper, lead, mercury, nickel, silver, and zinc) were found in concentrations exceeding their respective established criteria. In addition, arsenic, cadmium,

ND - Compound was not detected at or above the quantification limit.

NLE - No Level Established

chromium, and zinc were found in concentrations slightly exceeding their respective background concentrations. However, copper, lead, mercury, and nickel were found in concentrations below their respective maximum background levels.

4.2.14.5 Recommendations

Nine metals were detected above NJDEP criteria in the sediment sample collected at the outfall area. In addition, four metals (arsenic, cadmium, chromium, and zinc) exceeded their respective maximum background concentrations. The other five metals were detected below established background concentrations.

Although four metals were detected in sediment at levels exceeding NJDEP criteria and background, in the worst case the criteria were exceeded by a factor of three. Since the samples was taken at the outfall of the STP, the results are believed to be the worst case and the area of contamination is probably small. Access to this portion of Lafetra Creek is restricted although the stream is on the property boundary. The STP has not been used since 1941, and, presumably, the local ecology has reached an equilibrium. Therefore, since remediation would disrupt the ecology of the site, no further action will be taken.

PRE-1941 SANITARY TREATMENT PLANT
(Distribution of Contaminants in Site Sediment)

Main Post
PCB Transformers

Main Post
PCB Transformers

4.2.15 PCB Transformers

4.2.15.1 Site Location

During the 1993 investigation (WESTON, 1993) all locations where PCB transformers had formerly been located were inspected for evidence of spills. Eight sites were identified where a PCB transformer was either formerly located over soil and thus evidence of a spill could not be determined visually, or was formerly located on concrete and there was discoloration in the concrete. These locations are listed in Table 3.5-1. Figure 4.2-35 presents the Main Post transformer site sample locations.

4.2.15.2 Site History

All PCB transformers (contain greater than 500 ppm PCBs) have been removed from Fort Monmouth. However, the former locations of these transformers were not previously investigated for spilled PCBs.

4.2.15.3 Sampling Effort

As discussed in Subsection 3.5, soil samples were taken below pole-mounted transformers and on four sides of an outdoor pad-mounted transformer. Concrete samples were taken from stained areas on outdoor concrete pads or in interior vaults with concrete floors. All samples were analyzed for PCBs.

4.2.15.4 PCB Sampling Results

The results of the PCB transformer sampling are presented in Table 4.2-22. Four of the eight transformers sampled at the Main Post area were found to have PCBs in soil or concrete above applicable cleanup criteria.

All other transformers sampled in the Main Post either had results below detection limits, or had detectable levels of PCBs below applicable cleanup criteria.

Table 4.2-22
Results of Transformer Site Sampling on Main Post

Location (Building No.)	Sample ID	Method Detection Limit (mg/kg)	Medium	NJDEP Cleanup Criteria (mg/kg)	Total PCBs (mg/kg)
292	MPT5-TR01	0.24	Soil	0.49	**0.68**
686	MPT6-TR01	0.045	Soil	0.49	0.18
718	MPT4-TR01	0.051	Soil	0.49	0.06
1002	MPT7-CC01	2000*	Concrete	0.055	**8400**
1004	MPT8-TR01	0.45	Soil	0.49	ND
1208	MPT2-CC01	2000*	Concrete	0.055	**19000**
1209	MPT1-CC01	400*	Concrete	0.055	**1500**
1220	MPT3-TR01	0.045	Soil	0.49	ND
1220	MPT3-TR02	0.041	Soil	0.49	ND
1220	MPT3-TR03	0.047	Soil	0.49	0.06
1220	MPT3-TR04	0.045	Soil	0.49	0.09
1220	MPT3-CC01	0.04	Concrete	0.055	ND

Compounds exceeding NJDEP cleanup criteria are noted by bold numbers
ND - Indicates that the compound was not detected at the quantification limit.
* = Method detection limit unit exceeded the NJDEP criteria.

The following transformer sites had PCBs in soil or concrete above applicable cleanup standards:

- MP-062 (Building 292).
- Indoor transformer vault in Building 1002.
- Indoor transformer vault in Building 1208.
- Indoor transformer vault in Building 1209.

PCBs were detected in soils above applicable soil standards in the soil beneath transformer MP-062, which was a pole-mounted transformer on the northwest side of Building 292. The sample beneath the transformer contained PCBs above the NJDEP SCC.

The concrete samples from visibly stained areas in the indoor transformer vaults in Buildings 1002, 1208, and 1209 each contained PCBs above the proposed indoor surface cleanup criteria of 0.055 mg/kg.

4.2.15.5 Recommendations

PCB levels in stained concrete were found to exceed NJDEP guidance levels in indoor vaults at Buildings 1002, 1208, and 1209. PCBs were also detected above applicable soil standards in the soil beneath transformer MP-062 on the northwest side of Building 292.

Since the indoor vaults are normally locked and are accessible by a very limited number of facility personnel, and the stained concrete cannot be removed without significantly disrupting electrical service, remedial work will be performed when the transformers are removed from service and the stained areas are made accessible. A warning sign will be posted, and workers entering the vaults will be trained to take precautions to prevent contamination.

Because the concentration of PCBs is only slightly above the SCC, additional sampling will be conducted beneath the former location of transformer MP-062 to determine the vertical and horizontal extent of PCBs in soil. The soil sampling will be performed in accordance with the NJDEP *Technical Requirements for Site Remediation* (NJDEP, 1993). Personal protective clothing will be worn accordingly.

FIGURE 4.2-35
MAIN POST TRANSFORMER SITE
SAMPLE LOCATIONS

Charles Wood
Background Samples

4.3 CHARLES WOOD

This subsection presents a description of each Charles Wood site and presents the rationale for the sampling activities. The sites and the sampling effort are summarized in Table 4.3-1. Additional historical information on each site may be obtained from the *Investigation of Suspected Waste Sites at Fort Monmouth, New Jersey*, 1993.

The following subsections summarize the results of the sampling program that was implemented to characterize site conditions as specified in the report titled, *Site Investigation, Chemical Data Acquisition Plan (CDAP).* Although the field investigation was generally conducted in accordance with the CDAP, minor changes were made. These changes are summarized in Table 4.3-2. A total of 19 soil borings and 16 monitor wells were installed and 3 sediment and 2 surface-water samples were collected in the Charles Wood area. Soil and groundwater samples were collected from the borings and monitor wells and were analyzed for compounds determined to be characteristic of the wastes associated with each area, i.e., TCL and TAL analytes (see Tables 3.6-1 and 3.8-1). Appendix D presents the results of the Charles Wood sampling activities. Detailed information regarding the specific sampling protocols for each site is provided in the following subsections. In addition to the results of groundwater and soil analyses, the lithologic descriptions and water-level information are used to provide a hydrogeologic interpretation of the site where appropriate.

Figure 4.3-1 shows the location of the nine Charles Wood sites discussed in this subsection.

4.3.1 Background Samples

The locations of background sampling locations were selected in areas believed to be unaffected by past base activities. They were identified in the report *The Investigation of Suspected Hazardous Waste Sites at Fort Monmouth, New Jersey* (WESTON, 1993), which was approved by NJDEP. The purpose of the collection of background characterization data was to identify levels of chemicals that are naturally occurring.

Table 4.3-1

Site Investigation Summary — Charles Wood

Site Number	Site	Description	Potential Waste/ Contaminants	Past Samples and Analyses	Investigation Activities
CHARLES WOOD AREA					
CW-1	Wastewater treatment (lime pit)	4-m^3 tank containing limestone for neutralizing liquid waste from Bldg. 2700. Sludge removal periodically. Acid/base drains not currently used. Pit discharge to sewage system. Limestone was replaced in 1992; contractor took limestone off-site. Built with bldg. around 1952.	Solvents and metals.	Analyzed old limestone. Sludge analyzed; found organics and metals.	Installed 4 soil boring/monitor wells, 1 on each side of pit. Collected soil samples (2 to 3 per boring) from 7 to 9 ft. Analyzed for TCL +30/TAL. Sampled groundwater for same parameters.
CW-2	Wastewater treatment (lime pit)	Same as CW-1.	Solvents and metals.	Analyzed old limestone.	Same as CW-1.
CW-3, AOC-4	Landfill	Operated during 1940s. Site identified in IA now used for storage of contractor equipment and debris. Site was cleared in mid-1995.	Administrative waste and wood.	None.	Work postponed. Trenching is planned to evaluate subsurface conditions.
CW-3A	Landfill	Site in west was used for leaves and small debris, and by off-site dumpers. 1969 aerial photo shows disturbed soil at west site. One partially buried drum found. May have been used for demolition debris.	Unknown.	None.	Used geophysics (magnetics, EM-31, and GPR) to evaluate possible subsurface disposal near Pulse Power Building.
CW-4	Range (small arms)	Bldg. 2537. Indoor range. Cleaned and repainted in 1989. Has metal and sand bullet trap and filtered ventilation system. 3-ft diameter bare area to north of building with spent shells and bullet debris. Appears to be clean sand in back of building.	Lead.	None.	Collected 2 soil samples: 1 soil boring and 1 surface soil. Analyzed for TCL +30/TAL/TPH.
CW-5, AOC-3	Heavy metals	Former treatment plant. Discharged to stream. Sludge removed from sludge drying bed and plant cleaned, disinfected, and dismantled.	Heavy metals and cyanide.	Sludge analyzed in 1981 — no heavy metals.	Sampled sludge (see CW-9) for metals. Installed 2 soil borings in area of sludge drying beds. Sampled sediment at outfall. Analyzed for TCL +30/TAL/CN.

Table 4.3-1

Site Investigation Summary — Charles Wood (Continued)

Site Number	Site	Description	Potential Waste/ Contaminants	Past Samples and Analyses	Investigation Activities
CW-6	Pesticide Storage Building T-2044	Pesticides no longer stored in CW area. Use pesticide contractor. Pesticides were stored in steel igloo on concrete base. Was mixed outside of igloo and Bldg. T-2044.	Pesticides and herbicides.	Soil sampled in 1989 for pesticides. High levels of chlordane (up to 595 mg/kg) and trace amounts of others detected.	2 soil borings and installation of MW by Bldg. T-2044. Sampled soil, new well, and existing well MW-1 for TCL +30. Surface soil sample by ditch (TCL +30/TAL).
CW-9, AOC-3	Sludge dump	Sludge was placed on golf course. Sludge temporarily stored south of Bldg. T-2044. Currently has dark gray soil that had been removed near Hole 1.	Heavy metals.	None.	Installed 2 MWs for TCL +30/TAL. 9 surface soil samples for TAL, 1 soil boring for TCL +30/TAL.
AOC-7	Former hazardous waste storage area	Bldg. 2500 area. Has been used as storage area since 1961. Used as temporary hazardous waste storage area in 1987. Security guard overcome by fumes in 1987. Currently open field, no evidence of contamination.	Solvents, oil, and metals.	None.	Installed 6 soil borings. Analyzed for TCL +30.
PCB Transformers	Buildings	Several transformers in this area. All transformers were tested in 1990 for PCBs. Those with PCBs > 500 ppm were removed or remediated.	PCBs.	Transformers sampled — several >500 ppm. See transformer list.	Sampled PCB transformer locations.

Table 4.3-2

Differences Between Proposed and Actual Work at Charles Wood

Site	Differences
CW-1, CW-2	In accordance with work plan, only one sample was taken per soil boring instead of three because no contamination was detected during field efforts.
CW-3	Site had not been cleared prior to field effort; therefore, no investigation was conducted.
CW-4	Because contaminated soil had not been excavated prior to the field effort, one soil boring was installed instead of three surface soil samples.
CW-6, CW-9	The location of the monitor well was moved from site CW-6 to CW-9 because there was an existing well near the proposed location at CW-6. The existing monitor well at CW-6 was sampled. Surface soil sample SS-01 was analyzed for TAL metals, which was not originally proposed in the CDAP.

A total of five background soil borings, which were converted into monitor wells, were installed and two separate soil intervals were sampled from each boring. Two rounds of groundwater samples were collected from each location. Soil and groundwater samples were analyzed for the parameters listed in Tables 3.6-1 and 3.8-1. Background monitor wells were labeled as "B" wells, i.e., MW-06B. Charles Wood background locations are shown in Figure 4.3-2 and are labeled B-6, B-7, etc. Monitor well MW-06B was installed at background location B-6 and a similar practice was followed at the other background locations. Two background surface-water and sediment samples were also collected (Figure 4.3-2).

4.3.1.1 Hydrogeologic Interpretation

The five background monitor wells installed at the Charles Wood area were installed to depths ranging from 14 ft bgs to 15 ft bgs. Total depths were determined during drilling activities and were based on the depth where groundwater was encountered. The lithology and depth to groundwater varied between background locations, and this information is presented on the lithologic logs in Appendix A.

4.3.1.2 Soil Sampling Results

Soil samples were collected from two discrete intervals: 0 to 2 ft bgs and 2 ft bgs to depth to groundwater. Soil boring depths varied between the background locations, depending on the depth where water was encountered. The analytical results for background soil at specific sampling intervals are presented in Appendix D. Table 4.1-7 summarizes the maximum concentrations detected in background soil at Charles Wood.

VOCs

VOCs were not detected in Charles Wood background soil.

SVOCs

A total 10 SVOCs were detected below laboratory quantitation limits in background soil at the Charles Wood area (Table 4.1-7).

Pesticides/PCBs

Two pesticides (4,4'-DDE and 4,4'-DDT) were detected above the laboratory quantitation limit in background soil at the Charles Wood area.

Metals

As indicated in Table 4.1-7, 19 metals were detected in background soil at the Charles Wood area.

Cyanide

Cyanide was not detected in background soil at the Charles Wood area.

4.3.1.3 Groundwater Sampling Results

Two rounds of groundwater sampling were conducted at Charles Wood. The analytical results for groundwater samples from the individual sampling rounds are listed in Appendix D. Table 4.1-7 summarizes the maximum background concentrations detected in background water at Charles Wood.

VOCs

VOCs were not detected in Charles Wood background groundwater.

SVOCs

Two SVOCs were detected in background groundwater at Charles Wood (Table 4.1-7).

Pesticides/PCBs

Pesticides/PCBs were not detected in background groundwater at Charles Wood.

Metals

As indicated in Table 4.1-7, 19 total metals were detected in background groundwater at Charles Wood.

4.3.1.4 Surface-Water Sampling Results

Two upgradient surface-water samples, SS-B3 and SS-B4, were selected as background at Charles Wood (Figure 4.3-2). Contaminants detected in background surface water and corresponding sample identifications are presented in Appendix D. Table 4.1-9 summarizes the maximum detected concentrations in total and soluble background surface water at Charles Wood.

VOCs

VOCs were not detected in total background surface water. Soluble background surface-water samples at Charles Wood were analyzed for VOCs.

SVOCs

One SVOC, bis(2-ethylhexyl) phthalate, was detected below laboratory quantitation limits in background surface water (total) at Charles Wood. SVOCs were not analyzed for in soluble background surface-water samples at Charles Wood.

Metals

In total background surface water, 13 metals were detected above laboratory quantitation limits at Charles Wood. Similarly, 11 metals in soluble background surface water were detected above laboratory quantitation limits.

4.3.1.5 Sediment Sampling Results

Two upgradient sediment samples, SS-B3 and SS-B4, were selected as background at Charles Wood (Figure 4.3-2). Contaminants detected in background sediment and corresponding sample identifications are presented in Appendix D. Table 4.1-9 summarizes the maximum detected concentrations in background sediment at Charles Wood.

VOCs

VOCs were not detected in background sediment at Charles Wood.

SVOCs

Bis(2-ethylhexyl) phthalate and di-n-butyl phthalate were detected below the laboratory quantitation limits in Charles Wood sediment. Six PAHs were detected below laboratory quantitation limits in Charles Wood sediment.

Pesticides

Three pesticides (4,4′-DDD, 4,4′-DDE, and 4,4′-DDT) were detected in Charles Wood background sediment.

Metals

A total of 17 metals were detected in background sediment at Charles Wood above laboratory quantitation limits.

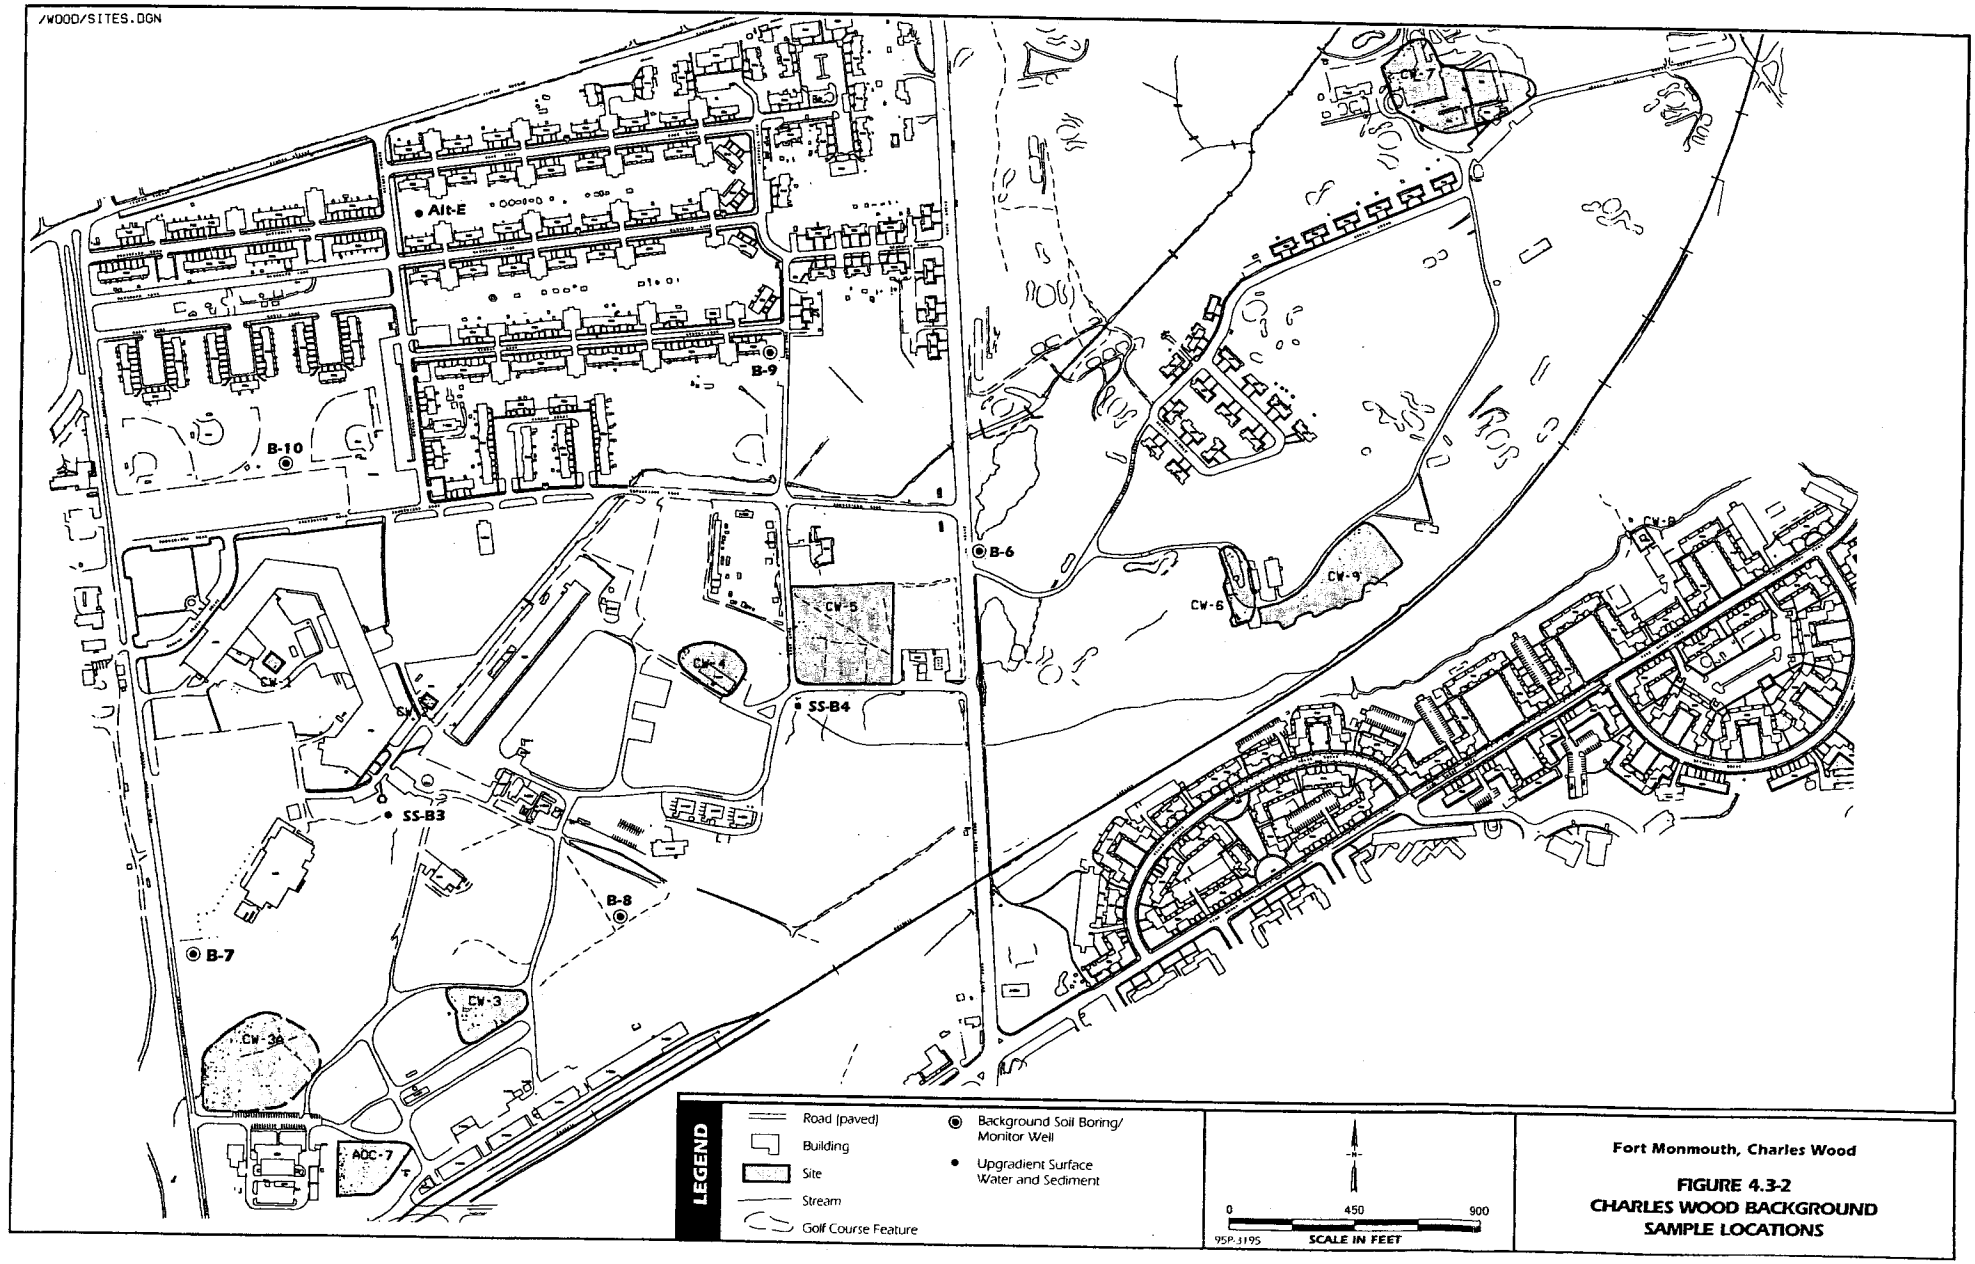
CHARLES WOOD SITE LOCATION MAP



Fort Monmouth, Charles Wood

FIGURE 4.3-2
CHARLES WOOD BACKGROUND SAMPLE LOCATIONS

Site CW-1

4.3.2 Wastewater Treatment Lime Pit 1 (CW-1)

4.3.2.1 Site Location

Wastewater Treatment Lime Pit 1 (CW-1) is located in the central area of the Hexagon Building (Building 2,700) at Charles Wood just east of the west wing of the building (Figure 4.3-3). The approximate area of CW-1 is 2,960 ft^2 (0.07 acre).

4.3.2.2 Site History

This lime pit (CW-1) was built concurrently with the Hexagon Building; construction was completed in 1952. This is one of two 4-cubic-meter (m^3) acid neutralization pits that contain limestone chips; the other pit (CW-2) is discussed in Subsection 4.3.3. Liquid wastes from the north and west wings of the Hexagon Building passed through this pit before being discharged to the sanitary sewer. Chemical wastes of up to 150 m^3 per day were generated from the shops and laboratories of the Hexagon Building; this waste output was reduced to 115 m^3 per day in June 1978 (USATHAMA, 1980). According to the IA, a licensed waste hauler was hired to dispose of concentrated wastes, such as etching solutions and organic solvents.

Each neutralization pit has a concrete floor and concrete block and mortar walls, and measures 7 ft by 13 ft wide by 8 ft high. The cover is constructed of concrete with a steel access panel. Several wooden baffles divide the pit into sections.

In October 1992, the pit was cleaned out, inspected, and the limestone chips replaced. A vacuum truck was used to remove the sludge and stones from the pit, after which the pit was rinsed with water. All sludge, stones, and rinse water were placed in drums and disposed of as a hazardous waste. At present, laboratory wastes are managed under the installation hazardous waste program, which forbids the discharge of these wastes to the sewer.

4.3.2.3 Sampling Effort

The elevated concentrations of halogenated hydrocarbons (HHCs) found in samples collected during the 1992 cleanout indicates the possibility that solvents were discharged into the lime pits. Neither concrete nor concrete block is an effective barrier to the migration of halogenated solvents. Halogenated solvents may have migrated from the lime pit into surrounding soils and possibly into groundwater. To investigate this potential, a monitor well was proposed for construction on each side of the lime pit (MW-26 through MW-29, shown in Figure 4.3-3); however, the proposed monitor well locations were slightly adjusted to avoid the buried conduit and underground water and acid lines. The wells were positioned accordingly to investigate the potential of halogenated solvent migration from the lime pit into the surrounding soil and groundwater. Continuous split-spoon samples were screened with an HNu or OVM. According to the CDAP, if any VOCs were detected, soil samples were to be collected from 7 to 9 ft bgs, from the interval with the highest instrument readings, and from just above the water table; otherwise, one sample was to be collected from 7 to 9 ft bgs from each boring. Because no elevated OVM readings were recorded, soil samples were collected from the 7 to 9 ft bgs interval only. Soil samples were analyzed for TCL +30 parameters and TAL metals. Two rounds of groundwater sampling were conducted from each well and analyzed for TCL +30 parameters and TAL metals.

4.3.2.4 Hydrogeologic Interpretation

Lithologic logs from monitor well locations MW-26 through MW-29 indicate that the lithology consists of a thin soil cover (0.3 ft) underlain by a well sorted olive-orange-brown medium-coarse-grained quartz sand.

Groundwater saturation was observed at approximately 7.5 ft bgs at all well locations. The four monitor wells were screened across the water table and were completed to 15 ft bgs at each location. Water-level elevation data, measured on 6 March 1995, prior to the March 1995 sampling round, indicate that the local groundwater flow direction is northeast, toward the Hexagon Research and Development Building. Based on groundwater elevation measurements,

monitor wells MW-28 and MW-29 are downgradient of the area under investigation (Figure 4.3-4).

4.3.2.5 Soil Sampling Results

Four soil samples, one in each monitor well borehole, were collected between 7 and 9 ft bgs and were analyzed for the parameters listed in Table 3.6-1. The analytical results for site soils, with the corresponding sample identifications, are listed in Appendix D. Table 4.3-3 compares the detected compounds with the NJDEP SCC, and then compares the results with the subsequent site-specific and Monmouth County maximum background limits.

VOCs

VOCs were not detected in site soil.

SVOCs

One SVOC (di-n-butyl phthalate) was detected above laboratory quantitation limits in site soil. However, the concentration of this compound was less than the NJDEP SCC and the maximum site-specific background.

Pesticides/PCBs

Pesticides were not detected above laboratory quantitation limits in site soil. PCBs were not detected in site soil.

Metals

As indicated in Table 4.3-4, all of the metals detected in site soil were found in concentrations below the NJDEP SCC, where established.

Compounds exceding NJDEP groundwater quality criteria are noted by bold numbers.

NJDEP groundwater quality criteria consist of the higher number between the PQL or STANDARD

*PQL - Practical Quantitation Limit -was used as the NJDEP groundwater quality criteria

ND - Indicates that the compound was not detected at the quantification limit

J - Indicates that the concentration value was estimated due to detection at or near the quantification limits

NLE - No Level Established

** - Method detection limit exceeds the NJDEP groundwater quality criteria

[2] - Monmouth County maximum background concentration

4.3.2.6 Groundwater Sampling Results

Monitor wells at site CW-1 were sampled for the analytical parameters listed in Table 3.8-1. The analytical results for the individual sampling rounds are listed in Appendix D. Table 4.3-4 compares the average concentrations of the detected compounds from the February and March sampling rounds with the NJDEP GWQC, and then compares the results with the subsequent site-specific and Monmouth County maximum background concentrations, where appropriate. Figure 4.3-5 presents the locations of the compounds detected above both NJDEP criteria and maximum background.

VOCs

Three VOCs (tetrachloroethene, trichloroethene, and 1,2-dichloroethene) were detected in site groundwater in concentrations exceeding the NJDEP GWQC. Tetrachloroethene was detected below the laboratory quantitation limit in MW-26 in the March sampling round only; however, the concentration exceeded the NJDEP GWQC. Trichloroethene was detected in MW-28 and MW-29 in both sampling rounds. 1,2-Dichloroethene (total) was detected in MW-29 only in both sampling rounds. VOCs were not detected in MW-27. Figure 4.3-5 presents the locations of the averaged concentration of compounds detected above the NJDEP GWQC and the maximum background levels established at Charles Wood.

SVOCs

SVOCs were not detected in the site monitor wells above laboratory quantitation limits and the NJDEP GWQC from either sampling round.

Pesticides/PCBs

Pesticides/PCBs were not detected in the site monitor wells from either sampling round.

Metals

As indicated in Table 4.3-4, of the 18 metals detected in site groundwater, 4 metals (aluminum, iron, manganese, and sodium) were found in concentrations exceeding the NJDEP GWQC; however, aluminum, iron, and manganese were detected in concentrations below the site-specific and Monmouth County maximum background levels. Although sodium was detected in concentrations greater than the site-specific background level, sodium was found in concentrations well below the Monmouth County maximum background level.

4.3.2.7 Recommendations

The soil sample results indicate that compounds of concern were either not detected or were below laboratory quantitation limits and NJDEP criteria.

The groundwater sampling results indicate that TCE, PCE, and 1,2-dichlorobenzene were detected in the groundwater downgradient of the site at levels that exceeded the NJDEP criteria.

Although NJDEP groundwater criteria were exceeded by three VOCs at this site, immediate remedial action is not required. The probable source of contamination has been eliminated since chemicals are not being disposed of in the pit. The pit was cleaned in October 1992 and the limestone sludge was removed and disposed of as a hazardous waste. Hazardous waste is currently collected for proper disposal off-site and waste is no longer disposed of in the pit. The groundwater is believed to flow toward the headwaters of Wampum Brook, and the shallow groundwater probably flows into Wampum Brook. There is no use of groundwater between the source and Wampum Brook. Surface-water samples were taken in Wampum Brook in the Charles Wood area and Mill Creek (as Wampum Brook is called further to the east) for use as background samples. No VOCs were detected in these samples, therefore, there is no immediate threat to human health.

The extent of VOC concentrations in groundwater will be investigated by soil-gas survey techniques. The soil-gas survey will be performed on an established grid pattern to estimate the

lateral extent of VOCs in the vicinity of the neutralization pit. The results of the soil-gas survey will be used to locate two additional monitor wells at the downgradient edge of the plume. DPW proposes that a long-term groundwater monitoring program be developed and implemented for the site. Aqueous samples would be collected and analyzed on a quarterly basis to further evaluate water quality conditions at the site. Groundwater samples would be collected from existing monitor wells and the two newly installed monitor wells. Compounds of concern identified in the first two rounds of sampling would be targeted for the monitoring program.

FTMM-23

4.3.3 Wastewater Treatment Lime Pit 2 (CW-2)

4.3.3.1 Site Location

Wastewater Treatment Lime Pit 2 (CW-2) is located southeast of the Hexagon Building (Building 2700) at Charles Wood near an electrical substation (Figure 4.3-3). The approximate area of site CW-2 is 1,751 ft^2 (0.04 acre).

4.3.3.2 Site History

Like Lime Pit 1, Lime Pit 2 (CW-2) was built concurrently with the Hexagon Building; construction was completed in 1952. Liquid wastes from the east and south wings of the Hexagon Building passed through this pit before being discharged to the sanitary sewer. Additional details, including the estimated quantities of wastes discharged through the lime pits, pit construction, and cleanout and replacement of the limestone, were discussed in Subsection 4.3.2.2.

Unlike Lime Pit 1, during cleanout this pit was found to have received sewage. A dye test was conducted and revealed that toilets from the guard shack and a bathroom for the handicapped near the east entrance were mistakenly connected to this pit. The plumbing has been rerouted to discharge the wastewater from the toilets directly to the sanitary sewer.

In October 1992, the pit was cleaned out, inspected, and the limestone chips replaced. A vacuum truck was used to remove the sludge and stones from the pit, after which the pit was rinsed with water. All sludge, stones, and rinse water were placed in drums and disposed of as a hazardous waste. At present, laboratory wastes are managed under the installation hazardous waste program, which forbids the discharge of these wastes to the sewer.

4.3.3.3 Sampling Effort

As in the case of Lime Pit 1, the elevated concentrations of HHCs in sludge, rinse, and grab samples suggest the possibility that solvents were discharged into the lime pits and that they may

have migrated from the lime pits into surrounding soils and possibly into groundwater. To investigate this potential, a monitor well was constructed on each side of the lime pit (MW-30 through MW-33, shown in Figure 4.3-3). Continuous split-spoon samples were screened with an HNu or OVM. According to the CDAP, if any VOCs were detected, soil samples were to be collected from 7- to 9-ft bgs (near the base of the neutralization pit), from the interval with the highest instrument readings, and from just above the water table; otherwise, one sample was to be collected from the 7- to 9-ft interval of each boring. Because no elevated OVM readings were recorded during borehole activities, one sample from the 7- to 9-ft bgs interval was collected for the required parameters. Soil samples were analyzed for TCL +30 parameters and TAL metals. Two rounds of groundwater samples were collected from each well and analyzed for TCL +30 parameters and TAL metals.

4.3.3.4 Hydrogeologic Interpretation

Lithologic logs from site monitor wells MW-30 and MW-31 indicate that the lithology consists of a thin soil cover (0.3 ft) underlain by fill material and reworked natural sediments. The components of the manmade materials consisted of quartz gravel and concrete, wood fragments, and pieces of old electrical conduit. The reworked natural sediments consisted of an interbedded green-gray silty fine-grained sand and green-gray fine-grained sandy silt. Lithologic logs from MW-32 and MW-33 indicate that the lithology consists of a thin soil cover (0.3 ft) underlain by shallow fill material and probable natural sediments. The filled material consisted of concrete fragments (to 2 ft bgs). The probable natural sediments consisted of an interbedded olive-gray moderately sorted silty fine-grained sand and a green moderately sorted very micaceous fine-grained sandy silt.

Groundwater saturation was observed between 1 and 8 ft bgs. The four monitor wells were screened across the water table and total depths ranged from 15 to 16 ft bgs. Water-level elevation data, measured on 6 March 1995, prior to the March 1995 sampling round, indicate that local groundwater flow is eastward (Figure 4.3-4). Based on groundwater elevation measurements, monitor wells MW-32 and MW-33 are downgradient of the former lime pit.

4.3.3.5 Soil Sampling Results

Four soil samples, one in each monitor well borehole, were collected and analyzed for the parameters listed in Table 3.6-1. Samples were collected between 7 and 9 ft bgs. The compounds detected in site soils, with the corresponding sample identifications, are listed in Appendix D. Table 4.3-5 compares site soil quality with the NJDEP SCC, and then compares the results with the subsequent site-specific and Monmouth County maximum background levels, where appropriate.

VOCs

Two VOCs (methylene chloride and 2-butanone) were detected in concentrations above laboratory quantitation limits. Methylene chloride and 2-butanone are common laboratory contaminants. Both compounds were detected in concentrations well below the NJDEP SCC.

SVOCs

Eight SVOCs were detected above laboratory quantitation limits in soil borings, but in concentrations below the NJDEP SCC. All SVOCs detected below quantitation limits were found in concentrations below the NJDEP SCC where established.

Pesticides/PCBs

Three pesticides (4,4'-DDE, 4,4'-DDD, and 4,4'-DDT) were detected in concentrations above laboratory quantitation limits, but were well below the NJDEP SCC.

One PCB (Aroclor-1254) in SB-30 was detected slightly above the laboratory quantitation limit as well as the NJDEP SCC (Figure 4.3-5). However, the PCB compound was not detected in groundwater samples from the corresponding well location, MW-30. PCBs were not detected in SB-31, SB-32, and SB-33.

Compounds exceeding NJDEP soil cleanup criteria are noted by bold numbers.
J- Indicates that the concentration value was estimated due to detection at or near the quantification limit
P- The percent difference between the results from two GC cloumns is greater than 25% the lower of the two values is reported
ND - Indicates that the compound was not detected at or below the quantification limits
NLE- No Level Established
ft bgs. - feet below ground surface.
Note: MDL's for metal analysis is actually the highest detection limit with potassium given as a range due to high variability.
[1] Monmouth County maximum background concentrations.
[2] NJDEP criteria are referenced in Site Remediation News, Winter 1995.
D - Surrogate or matrix spike recoveries were not obtained because the extract was diluted for analysis.

Metals

As indicated in Table 4.3-5, of the 18 metals detected in site soil, only beryllium in SB-33 was found at a concentration slightly exceeding the NJDEP SCC. Although beryllium was detected in a concentration greater than the established Monmouth County background level, the metal was detected below the site-specific background level.

4.3.3.6 Groundwater Sampling Results

Monitor wells at site CW-2 were sampled for the analytical parameters listed in Table 3.8-1. The analytical results for groundwater samples from the individual sampling rounds are listed in Appendix D. Table 4.3-6 compares the average concentrations of the detected compounds from the February and March sampling rounds with the NJDEP GWQC, and then compares the results with the site-specific and Monmouth County maximum background levels, where appropriate.

VOCs

Tetrachloroethene was the only VOC detected in site groundwater. The compound was detected in a concentration that was below the quantitation limit but slightly exceeding the NJDEP GWQC from the March sampling round only in MW-32 (Figure 4.3-5). Tetrachloroethene was not detected in MW-32 in the February sampling round.

SVOCs

One SVOC (di-n-butyl phthalate) was detected above the laboratory quantitation limit in MW-31 from the March sampling round. Di-n-butyl phthalate was detected well below the NJDEP GWQC. SVOCs detected below the laboratory quantitation limit were also detected below the NJDEP GWQC.

Table 4.3-6
Fort Monmouth - Charles Wood
Summary of Average Concentrations of Detected Compounds in Groundwater - Site CW-2

COMPOUND	METHOD DETECTION LIMIT (µg/L)	NJDEP GROUNDWATER QUALITY CRITERIA (µg/L)	MAXIMUM BACKGROUND CONCENTRATION (µg/L)	ANALYTICAL RESULTS (µg/L) SAMPLING DATE

Compounds exceeding NJDEP groundwater quality criteria are noted by bold numbers.

*PQL - Practical Quantitation Limit -was used as the NJDEP groundwater quality criteria

NLE - No Level Established

J - Indicates that the concentration value was estimated due to detection at or near the quantitation limits

ND - Indicates that the compound was not detected at or below the quantitation limit

** Method detection limit exceeded NJDEP groundwater quality criteria

[1] - Monmouth County maximum background concentrations.

Pesticides/PCBs

Pesticides/PCBs were not detected in the site monitor wells from either sampling round.

Metals

As indicated in Table 4.3-6, of the 16 metals detected in site groundwater, 3 metals (aluminum, iron, and manganese) were found in concentrations exceeding the NJDEP GWQC. In addition, iron was detected in concentrations greater than those determined for site-specific and Monmouth County maximum background at Charles Wood. The presence of iron in exceedence of the NJDEP GWQC may be attributable to the high concentrations of iron present in natural soil found in Monmouth County. Therefore, iron is not identified as a compounds of concern. Although manganese was detected in concentrations above the site-specific background level in MW-30, MW-32, and MW-33, manganese was found in concentrations below the Monmouth County background level. Aluminum was found in concentrations below both the site-specific and Monmouth County maximum background levels.

4.3.3.7 Recommendations

The results of the soil sampling indicate that one PCB compound (Aroclor-1254) was detected in SB-30 at a concentration slightly above the NJDEP SCC. PCB compounds were not detected in the other three soil borings. In addition, PCBs were not detected in groundwater samples in the corresponding well location, MW-30.

Groundwater sampling results indicate that PCE was detected in the groundwater in one of the four wells (MW-32) in one of the two sampling rounds at levels slightly exceeding the NJDEP GWQC.

Although NJDEP groundwater criteria were exceeded by one VOC at this site, immediate remedial action is not required. The source of contamination has been eliminated since chemicals are not being disposed of in the pit. The pit was cleaned in October 1992 and the limestone

sludge was removed and disposed of as a hazardous waste. Hazardous waste is currently collected for proper disposal off-site and waste is no longer disposed of in the pit. Shallow groundwater flows toward and discharges to the headwaters of Wampum Brook, as indicated by water-level measurements from site monitor wells. There are no known uses of groundwater at or downgradient of the site. Surface-water samples were taken in Wampum Brook in the Charles Wood area and Mill Creek (as Wampum Brook is called further to the east) for use as background samples. No VOCs were detected in these samples, therefore, there is no immediate threat to human health.

The extent of PCE concentrations in groundwater will be investigated by soil-gas survey techniques. The soil-gas survey will be performed on an established grid pattern to estimate the lateral extent of VOCs in the vicinity of the neutralization pit. The results of the soil-gas survey will be used to locate two additional monitor wells if necessary. DPW proposes that a long-term groundwater monitoring program be developed and implemented for the site. Aqueous samples would be collected and analyzed on a quarterly basis to further evaluate water quality conditions at the site. Groundwater samples would be collected from existing monitor wells and from the two newly installed monitor wells. Compounds of concern identified in the first two rounds of sampling would be targeted for the monitoring program. When the additional monitor wells are installed, soil samples will be collected for PCB analysis because of the detection of PCBs in a soil sample collected from SB-30.

Site CW-3

4.3.4 Landfill 3 (CW-3)

4.3.4.1 Site Location

Landfill 3 is located in the southeastern part of Charles Wood (Figure 4.3-6) and has been designated a construction area. The approximate area of Landfill 3 is 39,758 ft^2 (0.91 acre).

4.3.4.2 Site History

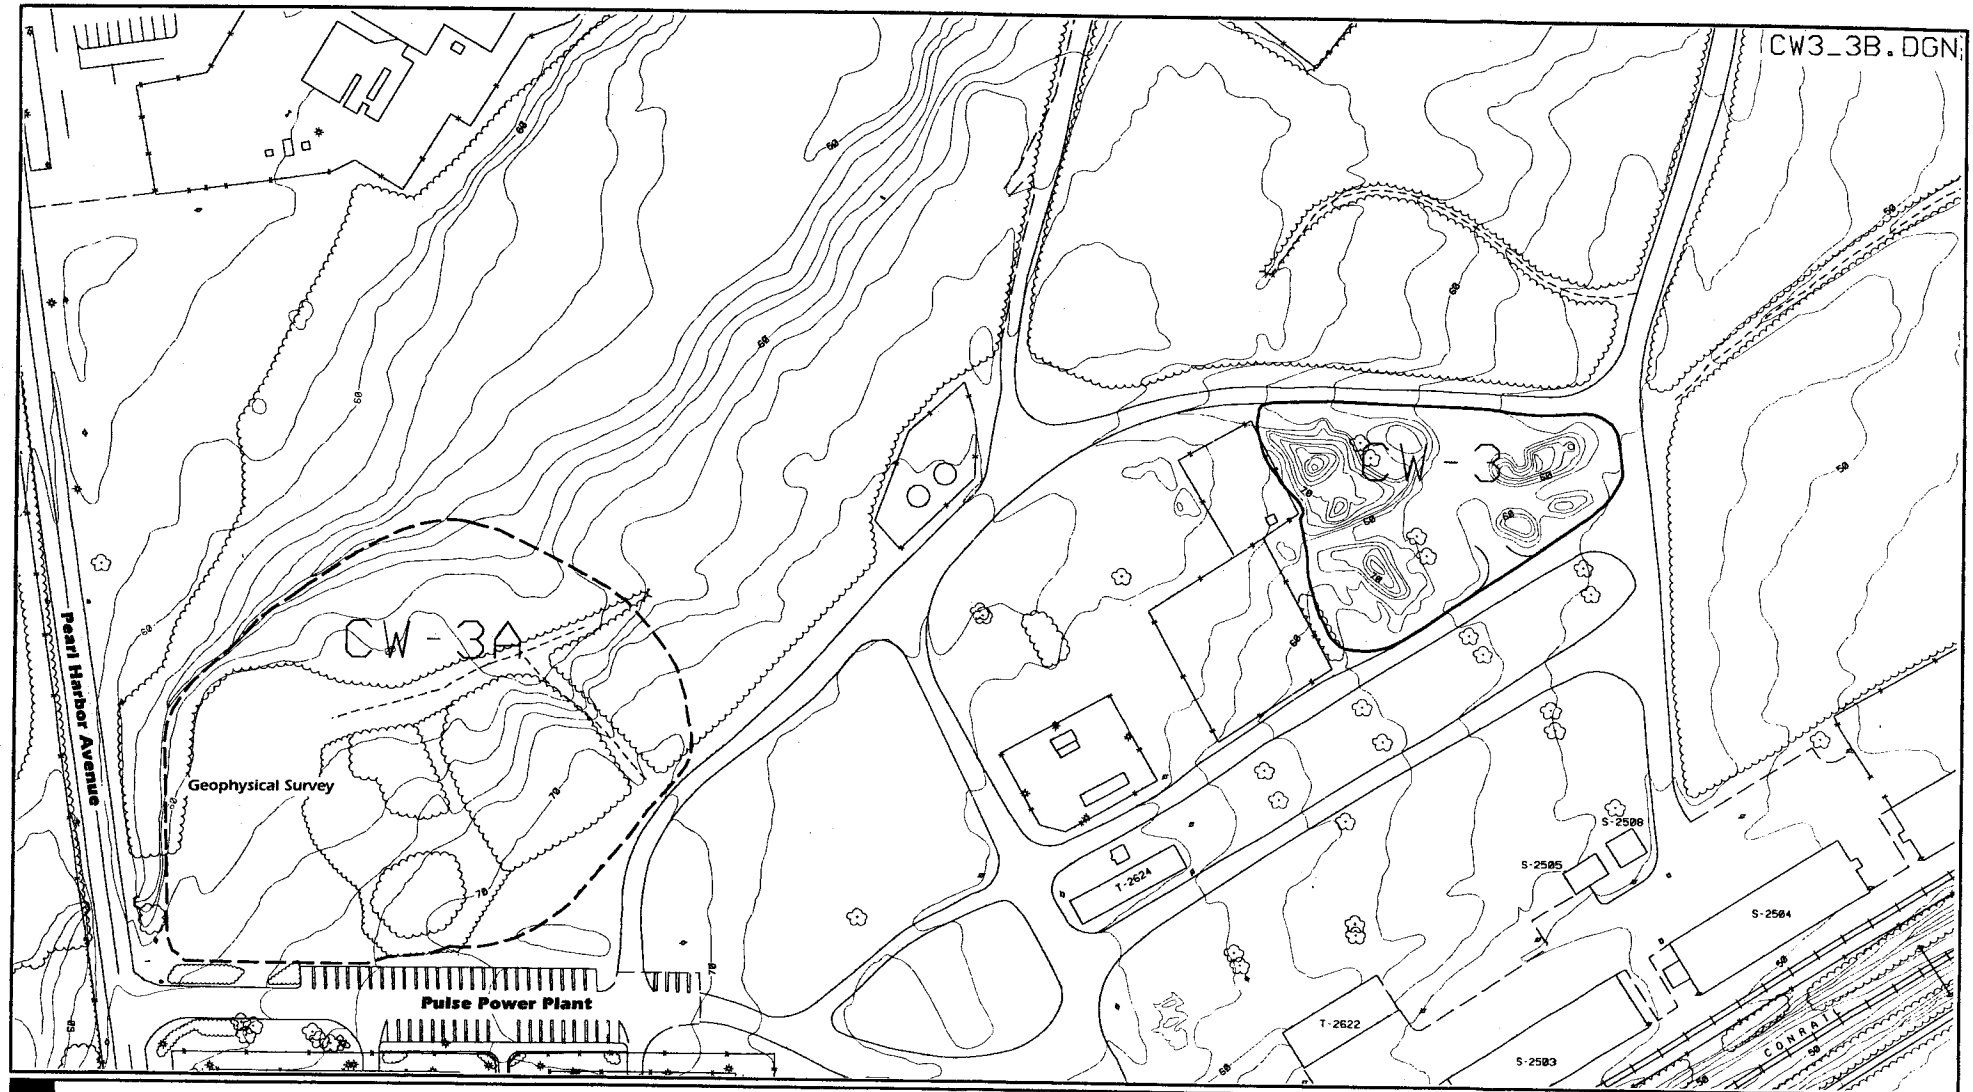
According to the IA, the Army Air Force used this area to dispose of administrative-type wastes and wood in the 1940s. Beginning in 1951, the aerial photographs show a cleared area used for storage. In 1981 and 1986, this area was relatively clear. During the 1993 site visit, the CW-3 area was being used as a construction rubble dump. Material observed included soil piles, brush, concrete, wood demolition debris, wood pallets, metal, and PVC pipe. There is no evidence of a subsurface landfill, and long-term Fort Monmouth employees said that this area was not used as a landfill.

4.3.4.3 Sampling Effort

Landfill 3 is shown in Figure 4.3-6. During the field investigation activities conducted between November 1994 and January 1995 at Fort Monmouth, construction rubble was present at site CW-3. The proposed sampling activities included collecting surface soil samples for TCL +30 parameters and TAL metal analysis if any evidence of soil staining was observed following the removal of the rubble. In addition, if high levels of chemical constituents were found in soils, monitor wells would be installed and sampled twice for TCL +30 parameters and TAL metals. Field sampling activities were postponed until the rubble could be removed. In June 1995, the construction rubble was removed. Exploratory trenches are planned to determine if any subsurface debris or soil staining is evident. However, because the area is believed to not have been used as a landfill, it is not anticipated that subsurface debris and soil staining will be found.

4.3.4.4 Recommendations

Investigation activities were not conducted as part of this investigation because of construction rubble that was present at the site during the field effort, which prohibited sample collection as planned. The rubble was removed and properly disposed of in June 1995 and exploratory trenches are planned to determine if any subsurface debris or soil staining is present. Field screening will be performed during excavation using a PID. NJDEP will be requested to send a representative to observe the investigation. In the absence of any elevated PID readings or evidence of subsurface debris, the excavation will be backfilled and no further action will be taken. If contamination is identified, then sampling will be conducted in accordance with the *Technical Requirements for Site Remediation* (NJDEP, 1993). Soil sample analytes will be collected and analyzed for the full range of contaminants.



Fort Monmouth, Charles Wood

FIGURE 4.3-6
LANDFILLS 3 (CW-3) AND 3A (CW-3A)

Site CW-3A

4.3.5 Debris Site (CW-3A)

4.3.5.1 Site Location

Debris Site CW-3A is located west of the CW-3 area, north of Pulse Power, Building 2707 (Figure 4.3-6). The approximate area of site CW-3A is 116,000 ft^2 (2.6 acres).

4.3.5.2 Site History

According to long-term Fort Monmouth employees, the area north of Pulse Power was used as a disposal area. The 1957 aerial photograph shows the CW-3A area with bare ground. According to *Fort Monmouth History and Place Names, 1917-1959*, 90 buildings at Charles Wood were razed in late 1955 and during 1956. It is possible that the demolition debris from these buildings was placed in this area. In the 1974 aerial photo, a steel igloo is visible on this area. By 1986, the western part of this area had not revegetated. During the 1993 site visit, some small debris was observed in the woods.

4.3.5.3 Sampling Effort

Site CW-3A is also presented in Figure 4.3-6. Surface geophysics were conducted in this area because it was not known if subsurface disposal had occurred in this area and in accessible cleared areas to the southeast in the construction areas. Magnetic and electromagnetic (EM-31) measurements were collected on 10-ft centers. GPR was also used to assess the degree of subsurface soil disturbance.

4.3.5.4 Geophysical Results

The geophysical investigation at Charles Wood site CW-3A utilized EM, MAG, and GPR methods to characterize the site. Prior to the investigation, a site walk revealed numerous metallic objects on the surface in the form of pipes, sheet metal, metal cans, and concrete, as well as nonmetallic objects such as asphalt and construction debris. The debris was noted and considered during data interpretation.

The EM survey revealed prominent anomalous signatures not attributed to surface debris at grid coordinates 40N to 70N/40E to 70E and 140N to 160N/190E to 210E. These anomalies are shown on the EM quadrature and in-phase contour plots, Figures 4.3-7 and 4.3-8, respectively, as either violet or blue contour intervals (high and low conductivity, respectively). These two EM anomalies are confirmed by the magnetometer survey as being ferrous material. As shown on the total magnetic field and magnetic gradient contour plots, Figures 4.3-9 and 4.3-10, respectively, these anomalies are represented as a high and low pair or magnetic dipole with violet and blue contour intervals. Other subtle anomalies exist throughout the area, as depicted on the EM in-phase plot in Figure 4.3-8, which may indicate metallic debris. However, the size and magnitude of these EM signals are negligible. Also, the EM quadrature plot (Figure 4.3-7) shows high apparent conductivity, represented by the violet contour interval, along the north and western borders of the site. This higher conductivity may be due to a subsurface change in lithology.

The GPR survey at CW-3A revealed chaotic reflectors within grid coordinates 40N to 70N/40E to 70E, confirming the EM and MAG anomalies at a depth of approximately 2 to 3 ft bgs. These chaotic reflectors are indicative of buried metallic debris and are shown on the GPR profile along 60N in Figure 4.3-10A.

4.3.5.5 Recommendations

Geophysical surveys indicated two areas where subsurface metallic debris may be present.

Exploratory trenching will be performed to investigate areas where subsurface metallic debris may be present. Field screening will be conducted with a PID during the excavation. NJDEP will be requested to send a representative to observe the excavation. In the absence of elevated PID readings or evidence of subsurface debris, the excavation will be backfilled and no further action will be taken. If contamination is identified, then sampling will be conducted in accordance with the *Technical Requirements for Site Remediation* (NJDEP, 1993). Soil sample analytes will be collected and analyzed for the full range of contaminants.

Site CW-4

4.3.6 Range (Small Arms) (CW-4)

4.3.6.1 Site Location

The small arms firing range is a one-story building (Building T-2537) located in the central portion of the Charles Wood area (Figure 4.3-11). The approximate area of site CW-4 is 32,000 ft^2 (0.7 acre). The range is used for indoor firing of small arms. The small arms are fired into a metal baffle that deflects the rounds down into a sand pit. Currently, the sand is sifted and spent rounds and shell-casings are disposed of off-site. The firing range area is ventilated by a blower through a filter. The filter currently used is a Flanders Filters Model No. 0-00J-C-11-00-CL-12-00-GGF. It has an efficiency of 95%, based on a di-octyl-phthalate (DOP) test. A manufacturer's representative stated that he believes this filter would be close to 100% efficient in removing the likely particulates generated in a firing range.

Spend rounds are visible at the surface of a bare patch of soil about 3 ft in diameter northeast of the building. A pile of sand is on the northwest side of the building.

4.3.6.2 Site History

Interviews with facility personnel indicate that the interior of the building is cleaned periodically. The building is currently in use.

4.3.6.3 Sampling Effort

The CW-4 site is presented in Figure 4.3-11. The facility personnel intend to excavate the soil at the bare patch until spent rounds and shell casings are no longer visible. Because contaminated soil had not been excavated prior to the field effort, one soil boring was installed in place of two of the three surface soil samples proposed in the CDAP. The soil boring was drilled near the debris pile to a depth of 8 ft bgs, where saturation was noted at approximately 6.1 ft bgs. The lithology consisted of an orange-brown sand with trace silt. The soil sample from soil boring SB-01 was collected at a depth of 4 to 6 ft bgs and analyzed for TCL +30 parameters, TAL metals, and TPHs. One surface soil sample was collected from the bottom of

the sand pile (sample SS-01) using a scoop to dig 6 inches below the bottom of the pile in one location. No firing debris was observed. Surface soil boring SS-01 was analyzed for TAL metals only.

4.3.6.4 Soil Sampling Results

Two soil samples were collected, one sample (SB-01) from the 2- to 6-ft bgs sampling interval in the soil boring at the debris pile, and one sample (SS-01) from the 0 to 0.5-ft bgs interval from the sand pile in the rear of the building. The samples were analyzed for the parameters listed in Table 3.6-1. The analytical results for site soils are listed in Appendix D. Table 4.3-7 compares the detected compound concentrations with the NJDEP SCC, and then compares the results with the subsequent site-specific and Monmouth County maximum background concentrations. In addition, the results were also compared with the impact to groundwater SCC because no monitor wells were installed at this site.

VOCs

VOCs were not detected in site soil.

SVOCs

SVOCs were not detected in site soil.

TPHs

Petroleum hydrocarbons were not detected in site soil.

Pesticides/PCBs

Pesticides/PCBs were not detected in site soil.

Zinc	0.41	1500	55.6	42.6	24.6

Compound exceeding NJDEP soil cleanup criteria are noted by bold numbers.

ND - Indicates that the compound was not detected at or below the quantification limits

NLE - No Level Established

Note: MDL's for metal anaysis is actually the highest detection limit with potassium given as a range due to high variability.

[1] Monmouth County maximum background concentrations.

[2] NJDEP criteria are referenced in Site Remediation News, Winter 1995.

Metals

As indicated in Table 4.3-7, of the 20 metals detected in site soil, only lead was found in a concentration exceeding the NJDEP SCC. In addition, lead was detected in a concentration in SB-01 greater than the site-specific and Monmouth County maximum background levels for Charles Wood. The presence of lead in exceedance of criteria in the soil is reflective of the site's use for disposal of spent rounds. Figure 4.3-12 shows the locations of the compounds detected above the NJDEP SCC and above the established background levels for Charles Wood.

4.3.6.5 Recommendations

Soil sampling results indicate that only lead was detected at a concentration exceeding the NJDEP SCC at the spent round disposal area.

DPW has submitted the necessary documentation to HQAMC/AEC to obtain the proper funding to remediate the site in FY 1996. Depending on funding availability, the affected soil will be removed and confirmation samples will be collected at the base of the excavation.

The contaminated soil will be removed and disposed of in accordance with applicable regulations. The area of contamination is approximately 8 feet in diameter. The estimated depth of excavation is assumed to be 7 feet. Excavation will be performed in conjunction with confirmatory sampling to ensure that NJDEP SCC are achieved. It is estimated that 17 yd^3 of soil will be excavated, assuming that soil is excavated to a depth of 7 feet. NJDEP will be requested to send a representative to observe the excavation.

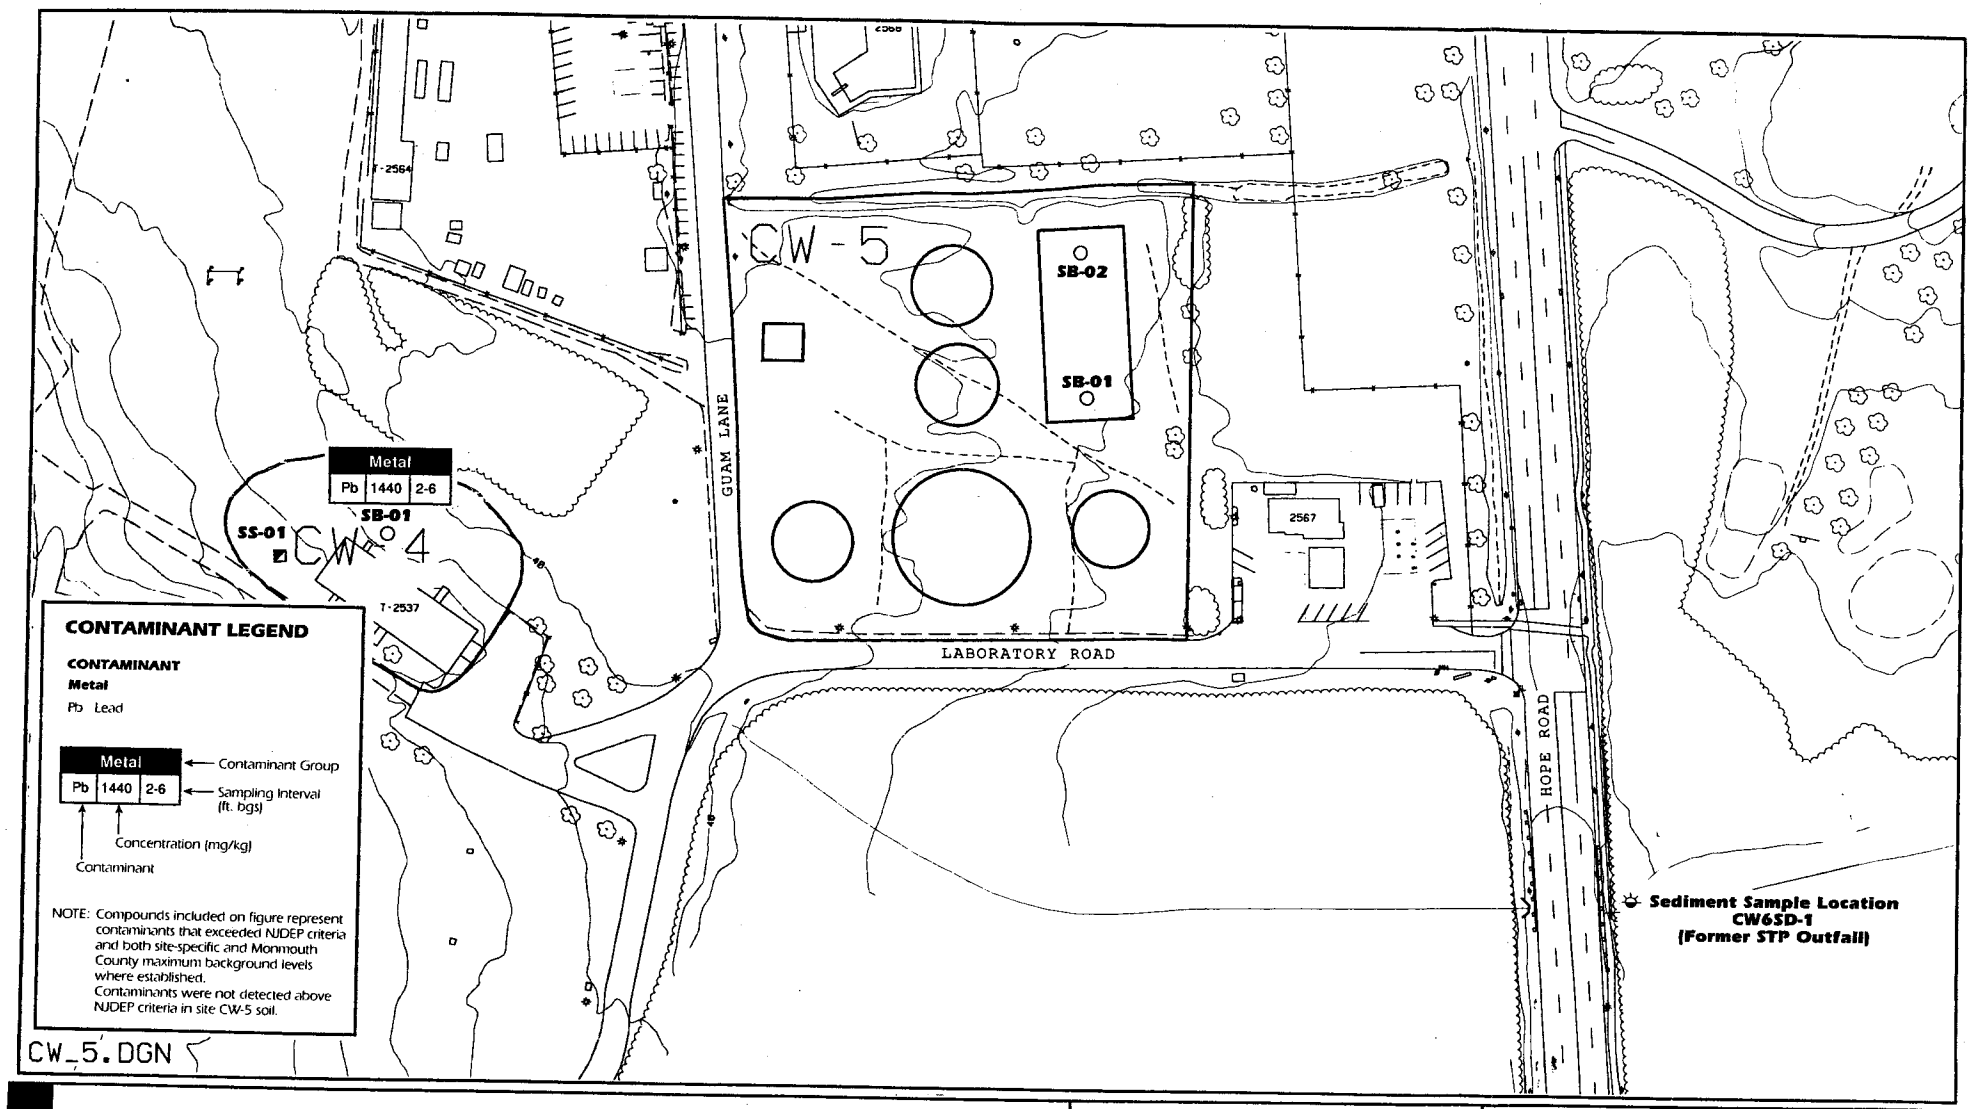
FIGURE 4.3-11
SMALL ARMS RANGE (CW-4) AND FORMER SANITARY TREATMENT PLANT (CW-5) SAMPLING LOCATIONS



Fort Monmouth, Charles Wood

FIGURE 4.3-12
SMALL ARMS RANGE (CW-4) AND FORMER SANITARY TREATMENT PLANT (CW-5) DISTRIBUTION OF CONTAMINANTS IN SITE SOILS

Site CW-5

4.3.7 Former Sanitary Treatment Plant (CW-5)

4.3.7.1 Site Location

The former STP at Charles Wood was located in the southwest corner of the area bounded by Hope Road to the east, Corregidor Road to the north, Guam Lane to the west, and Laboratory Road to the south (Figure 4.3-11). The approximate area of the STP was 134,080 ft^2 (3.1 acres).

4.3.7.2 Site History

The Charles Wood STP was built in 1942 to handle 800,000 gallons of sewage per day. As described in the IA, this STP consisted of a grit chamber screen, comminutor, primary and secondary settling tanks, biofilters, and a baffled contact chlorination tank. Sludge was treated in two anaerobic digesters and discharged to underdrained sand beds for final drying. Supernatant liquid from digester sludge and drainage from the sand beds were recycled through the STP for additional treatment. The chlorinated effluent was discharged to a tributary of Wampum Brook on the east side of Hope Road. Sludge went to the golf course and to landfills. This STP was closed on 29 October 1975 when the Charles Wood sewer system was connected to the NMCRSA system. In 1981, all sludges and supernatant liquids were removed from the STP, and the facility was cleaned and disinfected. The removal contractor was Modern Transportation Co. of Kearny, New Jersey. Mercury used in the distributor seal on the biofilter was removed and disposed of by the Directorate of Logistics. The physical facility was demolished in 1983. In 1993, a youth center was constructed on this site.

4.3.7.3 Sampling Effort

The CW-5 site is presented in Figure 4.3-11. One sediment sample from the outfall area east of Hope Road was collected and analyzed for TCL +30 parameters, TAL metals, and cyanide. Two soil borings were completed and soil samples collected in an effort to evaluate the impact of the former sludge-drying beds on soil quality in the original land surface. Soil borings SB-01 and SB-02 were completed to 8- and 6-ft bgs, respectively. Saturation was observed between 5.5- and 7-ft bgs. The lithology consisted of a yellow-brown gravelly sand fill underdrain by a

greenish-gray silty sand. Soil boring samples were analyzed for TCL +30 parameters, TAL metals, and cyanides.

4.3.7.4 Soil Sampling Results

Two soil samples, one in each borehole, were collected from the 6- to 8-ft bgs sampling interval and were analyzed for the parameters listed in Table 3.6-1. The analytical results for site soils are listed in Appendix D. Table 4.3-8 compares the detected compounds with the NJDEP SCC, and then compares the results with the site-specific and Monmouth County maximum background levels. In addition, the detected compounds were also compared with the impact to groundwater SCC because no monitor wells were installed at this site.

VOCs

One VOC (2-butanone) was detected in SB-01. The concentration was detected well below both applicable SCC (residential and impact to groundwater) and background. 2-Butanone is a common laboratory contaminant.

SVOCs

One SVOC was detected above the laboratory quantitation limit in site soil in SB-01, but below the NJDEP SCC and background. In addition, all compounds detected below quantitation limits were also detected well below both SCCs.

Pesticides/PCBs

Five pesticides and two PCBs were detected in concentrations above laboratory quantitation limits in SB-01 and SB-02, but were detected well below both of their respective SCCs and background.

[2] NJDEP criteria are referenced in Site Remediation News, Winter 1995.

Metals

As indicated in Table 4.3-8, all metals detected in site soils were found in concentrations below the NJDEP SCC, where established.

4.3.7.5 Sediment Sampling Results

The STP sediment sampling location was determined to be freshwater because the area is not tidally influenced. One sediment sample, CW6SD-1, was collected at the former outfall of the STP (Figure 4.3-11).

VOCs

VOCs were analyzed for but were not detected in site sediment samples.

SVOCs

One SVOC [bis(2-ethylhexyl) phthalate] was detected above the laboratory quantitation limit from location C6SD1. NJDEP sediment guidance values are not established for this compound. This compound is a common laboratory contaminant.

Pesticides/PCBs

Three pesticide compounds (4,4'-DDD, 4,4'-DDT, and 4,4'-DDE) were detected in concentrations exceeding the NJDEP sediment guidance criteria. However, the concentrations were found in levels below their respective background concentrations. PCBs were not detected in site sediment samples.

Metals

As indicated in Table 4.3-9, no metals were detected in concentrations greater than the NJDEP sediment guidance criteria.

4.3.7.6 Recommendations

Three compounds (4,4′-DDT, 4,4′-DDD, and 4,4′-DDE) were detected in the sediment at levels that were above the NJDEP sediment guidance criteria but below background. Soil results were below the NJDEP SCC and established maximum background.

No further action will be taken.

Compounds detected above NJDEP Sediment Guidance are bolded.

*- NOAA (1990) ER-L guidance. Values for DDE and DDD are not presented in NJDEP Sediment Quality Evaluations (1991).

** - Standards developed using equilibrium partioning approach in accordance with NJDEP Guidance for Sediment Quality Evaluation (1991). Total organic carbon concentrations of 1% assumed based on organic carbon content detected in adjacent sample.

ND - Compound was not detected at or above the quantification limit.

NLE - No Level Established

J - Concentration was estimated due to detection at or below the quantification limit

P - The percent difference between the results from the two GC columns is greater than 25%, the lower of the two values is reported

Site CW-6

4.3.8 Pesticide Storage Building T-2044 (CW-6)

4.3.8.1 Site Location

Building T-2044 is part of a small complex of buildings in the south-central portion of the Charles Wood area. The complex consists of Building T-2044, Building T-2070, and two metal igloos. The buildings are currently used to store golf course maintenance and landscaping equipment, such as mowers and tractors. The approximate area of site CW-6 is 25,000 ft^2 (0.6 acre).

4.3.8.2 Site History

The golf course maintenance complex may predate the purchase of the golf course by the Army. Pesticides and herbicides were formerly stored and mixed in this area. The IA contains a 1979 inventory of pesticides and herbicides that were used on the golf course and stored in Building T-2044. Some of the pesticides that were present in significant quantities are malathion, floriable sevin, resmithrin, Borocel IV, chlordane, and Dibrom. The IA also discusses a pest control program that was in effect in 1979. The compounds that were used in large quantities include carbaryl (sevin), malathion, chlordane, and diazinon. Some of the herbicides mentioned in the IA include 2,4-D, Dacthal, 2,4,5-T, and sodium arsenite.

The course groundskeeper, who has been part of the grounds crew for 33 years (1960 to 1993), said pesticides and herbicides were kept in a metal igloo and were mixed in two areas marked A and B in Figure 4.3-13. Area A is on a currently grass-covered area south of the igloo. At area A two USTs were excavated and the chlordane-contaminated soil was disposed of in spring 1995. Area B is on pavement near the office door in T-2044. This paved area has a drain that empties into a ditch in the woods immediately behind T-2044. The supervisor said that pesticide containers were not rinsed, but were disposed of to the landfill as is. Prior to 1980, the containers would have been disposed of at a landfill on the Main Post, such as site M-8.

Pesticides and herbicides are not currently stored or mixed on-site. The facility has hired an outside contractor to come in and apply pesticides and herbicides.

4.3.8.3 Sampling Effort

Limited sampling in 1989 determined that NJDEP SCC were exceeded in one soil sample. The sampling report did not clearly identify the location of the sample.

To confirm the existence of contamination and evaluate the effect on groundwater, two soil borings were completed at locations where pesticides mixing was believed to have occurred. These locations are just north of Building T-2044 (SB-02) and just south of the pavement that extends in front of Building T-2044 (SB-34). The borings were advanced to the water table and soil samples were taken at 6 to 12 inches and at 2 feet and analyzed for TCL +30 parameters. One surface soil sample was taken in the runoff ditch that runs into the woods southwest of Building T-2044 (Figure 4.3-13).

One monitor well was installed in these borings (MW-34), shown in Figure 4.3-13, and groundwater samples were collected in two sampling rounds and analyzed for TCL +30 parameters. Furthermore, a pre-existing monitor well (MW-01) was sampled twice for TCL +30 parameters in an effort to further evaluate the nature and extent of contamination on site groundwater quality.

The location of the monitor well proposed in the CDAP (MW-35) at site CW-6 was moved to site CW-9 because an existing monitor well was located near the proposed well location.

4.3.8.4 Hydrogeologic Interpretation

The lithologic logs from MW-34 indicate that the lithology consists of a thin soil cover (0.3 ft) underlain by a brown fine-medium-grained sand with olive-brown sand laminae. Saturation was observed at approximately 4 ft bgs. Monitor well MW-34 was screened across the water table and was drilled to 14.5 ft bgs. Water-level elevation data, measured on 6 March 1995, prior to the March sampling round, indicate that local groundwater flow is east toward site CW-9 (Figure 4.3-14).

The following subsections summarize the soil and groundwater analytical results for site CW-6.

4.3.8.5 Soil Sampling Results

A total of four soil samples were collected: two in the MW-34 borehole, one in SB-02, and one in SS-01. The soil samples were analyzed for the parameters listed in Table 3.6-1. Sample depths of soil borings were 0 to 2 and 2 to 4 ft bgs in SB-34 and 0.5 to 1 ft bgs in SB-02. The surface soil sample was collected from 0 to 0.5 ft bgs. The analytical results for site soils at specific sampling intervals are listed in Appendix D. Table 4.3-10 compares the detected compounds with the NJDEP SCC, and then compares the results with the site-specific and Monmouth County maximum background concentrations, where appropriate.

VOCs

VOCs were not detected in site soil.

SVOCs

SVOCs were not detected above laboratory quantitation limits in site soil.

Pesticides/PCBs

Seven pesticides were detected above laboratory quantitation limits in either SB-34, SB-02, and SS-01 from predominantly the 0- to 2-ft bgs sampling interval. In addition, one compound (dieldrin) was detected in a concentration exceeding the NJDEP SCC and background in SB-34 (0 to 2 ft bgs). Subsequently, dieldrin was not detected in groundwater samples from MW-34. Three of the compounds detected were below the NJDEP SCC and three do not have established criteria. PCBs were not detected in site soil. Figure 4.3-15 presents the locations of compounds detected above maximum background and the NJDEP criteria.

Compounds exceeding NJDEP soil cleanup criteria are bolded
NA - Not Analyzed; NS - Not Sampled
ND - Compound was not detected at or below the quantification limits
J - Indicates that the concentration value was estimated due to detection at or near the quantification limits
NLE - No Level Established
C - Pesticide identification was confirmed by GC/MS
D - Surrogate or matrix spike recoveries were not obtained because the extract was diluted for analysis
P - The percent difference between the results from two GC columns is greater than 25%, the lower of the two values is reported
R - Data rejected, URS The Data Validator

Note: MDL's for metal anaysis is actually the highest detection limit with potassium given as a range due to high variability.

Note: Metals were analyzed (SS-01), but were not proposed in the scope of work.

(1) - VOC/SVOC's were collected from 6" to 12" bgs, pesticides and metals were collected from 0"-6" bgs.

[2] Monmouth County maximum background concentrations.

[3] NJDEP criteria are referenced in Site Remediation News, Winter 1995.

Metals

As indicated in Table 4.3-10, of the 18 metals detected in site soils, only cadmium was found in a concentration exceeding the NJDEP SCC in SS-01. In addition, cadmium was detected in a concentration greater than that determined for site-specific and Monmouth County maximum background at Charles Wood. However, in accordance with the NJDEP *Cleanup Standards for Contaminated Sites* (NJDEP, 1992), the arithmetic mean of cadmium was calculated from the 10 surface soil samples at sites CW-6 and CW-9, since the samples were collected within the same sampling interval (0 to 6 inches). The arithmetic mean or concentration was then compared with the NJDEP SCC and established background. The arithmetic mean (1 mg/kg) was found at a level equal to the NJDEP SCC (1 mg/kg). However, sites CW-06 and CW-09 are located on a golf course. *A Summary of Selected Soil Constituents and Contaminants at Background Locations in New Jersey*, 1993, provides a separate background concentration level for cadmium in golf course areas. When comparing the arithmetic mean of the analytical results at the two sites with the arithmetic mean for cadmium on golf courses in Table 9 of that document (2.26 mg/kg), the analytical result is found in a concentration below established background. Cadmium is reported in higher concentrations on golf courses due to the direct application of fertilizers, herbicides, and pesticides (Field et al., 1993). Therefore, cadmium is not considered a compounds of concern. Although metals were sampled for in surface soil location SS-01, a metals analysis was not proposed in the original scope of work.

4.3.8.6 Groundwater Sampling Results

Monitor wells MW-34 and MW-1 were sampled for the analytical parameters listed in Table 3.8-1. The analytical results for groundwater samples from the individual sampling rounds are listed in Appendix D. Table 4.3-11 compares the average concentrations of the detected compounds from the February and March sampling rounds with the NJDEP GWQC, and then compares the results with the subsequent site-specific and Monmouth County maximum background concentrations, where appropriate.

Table 4.3-11
Fort Monmouth - Charles Wood
Summary of Average Concentrations of Detected Compounds in Groundwater - Site CW-6

COMPOUND	METHOD DETECTION LIMIT (µg/L)	NJDEP GROUNDWATER QUALITY CRITERIA (µg/L)	MAXIMUM BACKGROUND CONCENTRATION (µg/L)	ANALYTICAL RESULTS (µg/L) SAMPLING DATE	
				MW34 2/10/95, 3/13/95 (avg.)	MW01 5/10/95, 5/27/95 (avg.)
VOC (µg/L)					
Benzene	2.4**	1*	ND	ND	**8**
Ethylbenzene	3.1	700	ND	ND	1J
Xylene (total)	3.8	40	ND	ND	2J
Pesticide and PCB's (µg/L)					
4,4'-DDD	0.097	0.1	ND	ND	0.086J
gamma-chlordane	0.046	NLE	ND	ND	.035JP
alpha-chlordane	0.046	NLE	ND	ND	0.0545

Compounds exceeding NJDEP groundwater quality criteria are noted by bold numbers.

NJDEP groundwater quality criteria consist of the higher number between the PQL or STANDARD

*PQL - Practical Quantitation Limit -was used as the NJDEP groundwater quality criteria

ND - Indicates that the compound was not detected

J - Indicates that the concentration value was estimated due to detection at or near the detection limits

** - Method detection limit exceeded NJDEP groundwater quality criteria

P - Percent difference between the results from the GC columns is greater than 25%, the lower of the two values is reported

VOCs

One VOC (benzene) was detected above the laboratory quantitation limit in MW-1 from the February sampling round only. In addition, benzene was found in a concentration exceeding the NJDEP GWQC. Figure 4.3-15 presents the locations of the compounds detected above both background and criteria.

SVOCs

SVOCs were not detected above laboratory quantitation limits in site monitor wells MW-34 and MW-1 from either sampling round. In addition, SVOCs were detected below the NJDEP GWQC.

Pesticides/PCBs

One pesticide (alpha-chlordane) was detected in a concentration slightly above the laboratory quantitation limit in MW-1; however, NJDEP GWQCs are not established for alpha-chlordane. PCBs were not detected in site monitor wells from either sampling round.

4.3.8.7 Recommendations

The pesticide dieldrin and the metal cadmium were detected in the soil at two different locations, each at levels that exceeded NJDEP SCC and background. However, the average concentrations of dieldrin and cadmium in surface soil samples at CW-6 and CW-9 did not exceed the NJDEP SCC. Cadmium is typically present at elevated levels at golf courses. Groundwater samples indicated that benzene was detected in the existing monitor well (MW-1), which is attributed to a previously removed UST. Benzene was not detected in downgradient wells. Pesticides were not detected in any groundwater samples above NJDEP criteria.

NJDEP groundwater criteria were exceeded for one VOC, but the measured value was just slightly above the GWQC. Therefore, no immediate remedial action is necessary.

DPW proposes that a long-term groundwater monitoring program be developed and implemented for the site. Aqueous samples would be collected and analyzed on a quarterly basis to further

evaluate water quality conditions at the site. Groundwater samples would be collected from existing monitor wells. Compounds of concern identified in the first two rounds of sampling would be targeted for the monitoring program.

AND SLUDGE DUMP (CW-9)
DISTRIBUTION OF CONTAMINANTS IN SITE SOIL

Site CW-9

4.3.9 Sludge Dump (CW-9)

4.3.9.1 Site Location

The sludge dump (CW-9) as identified in the IA is located in the southern part of Charles Wood, south and southeast of Building 2070 and west of green 11 and tee 12 of the golf course (Figure 4.3-13). The approximate area of site CW-9 is 79,933 ft^2 (1.8 acres).

4.3.9.2 Site History

Since the 1940s, sludge generated at the STPs has been stored in this area before being used as a soil conditioner and fertilizer on the golf course. Sludge piles are visible in the 1957, 1961, 1974, and 1981 aerial photographs. During the 1993 site visit, a pile of sludge removed from fairway 1 on the golf course was observed south of Building 2070. According to long-term Fort Monmouth employees, at least three other fairways (8, 10, and 11) have 4 to 5 inches of sludge over the native sand; sludge may have been used to fill in low areas.

4.3.9.3 Sampling Effort

Two monitor wells were installed (MW-35 and MW-36), one soil sample from soil boring SB-01 and nine from surface soil locations SS-01 through SS-09 were collected, and two rounds of groundwater sampling were conducted in an effort to evaluate the impact of past site activities on soil and groundwater quality. Monitor wells MW-35 and MW-36 and soil boring SB-01 were analyzed for TCL +30 parameters and TAL metals. Surface soil locations SS-01 through SS-09 were analyzed for TAL metals only. The sampling locations are presented in Figure 4.3-13. MW-35 was relocated from site CW-6 because an existing monitor well was located at the proposed well location. The monitor well (MW-35) was then relocated to a downgradient location at CW-9 to monitor groundwater quality downgradient of the area under investigation.

4.3.9.4 Hydrogeologic Interpretation

Lithologic logs from MW-35 and MW-36 indicate that the lithology consists of a thin soil cover (0.3 ft) underlain by an orange-olive-brown predominantly medium-grained quartz sand with silt laminae. Saturation was observed at 4 ft bgs. Monitor wells were screened across the water table, with total depths of 14.5 and 14 ft bgs in MW-35 and MW-36, respectively. Water-level elevation data, measured on 6 March 1995, prior to the March 1995 sampling round, indicate that the local groundwater flow direction is east (Figure 4.3-14). Based on groundwater elevation measurements, monitor wells MW-35 and MW-36 are downgradient of the area under investigation.

4.3.9.5 Soil Sampling Results

One soil sample was collected from the 2- to 4-ft bgs sampling interval in a boring installed to a depth of 6 ft bgs. One sample from each surface soil location was collected from the 0- to 0.5-ft bgs interval. The soil samples collected were analyzed for the parameters listed in Table 3.6-1. The analytical results for site soil are listed in Appendix D. Tables 4.3-12 and 4.3-13 compare the compounds detected with the NJDEP SCC, and then compare the results with the subsequent site-specific and Monmouth County maximum background concentrations, where appropriate.

VOCs

VOCs were not detected in site soil.

SVOCs

SVOCs were not detected above laboratory quantitation limits in site soil.

Compounds exceeding NJDEP soil cleanup criteria are noted by bold numbers.
ND - Compound was not detected at or below the quantitation limits
NLE - No Level Established
Note: MDL's for metal analysis is actually the highest detection limit with potassium given as a range due to high variability.
[1] Monmouth County maximum background concentrations.
[2] NJDEP criteria are referenced in Site Remediation News, Winter 1995.
Note: Metals detected in a duplicate sample from SS-01 were detected below the NJDEP SCC.

Pesticides/PCBs

Two pesticides (4,4'-DDE and 4,4'-DDT) were detected above laboratory quantitation limits in SB-01. Both compounds were detected well below their respective SCCs. PCBs were not detected in site soil.

Metals

As indicated in Tables 4.3-12 and 4.3-13, of the 21 metals detected in site soil, only beryllium and cadmium were found in concentrations equal to or greater than the NJDEP SCC. In addition, cadmium was detected in SS-07 at a concentration (Table 4.3-13) greater than the site-specific and Monmouth County maximum background levels established at Charles Wood. However, in accordance with NJDEP *Cleanup Standards for Contaminated Sites* (NJDEP, 1992), the concentration of cadmium at sites CW-06 and CW-09 were averaged and then compared to the NJDEP SCC and established background. The average concentration of cadmium was found to be equal to the SCC when compared with the soil sampling results in the area. Cadmium was not considered to be of a high concentration (see "Metals" in Subsection 4.3.8.5). Cadmium was not detected at any other surface soil location. Although beryllium was found in a concentration greater than the Monmouth County maximum background level, beryllium was detected in a concentration below the site-specific level. Beryllium was found at only one location (SS-09) at a concentration equal to the NJDEP SCC. The concentration of beryllium was also averaged and when compared to the NJDEP SCC, was found at a concentration below the NJDEP SCC and maximum background.

4.3.9.6 Groundwater Sampling Results

Monitor wells at site CW-9 were sampled for the analytical parameters listed in Table 3.8-1. Table 4.3-14 compares the average concentrations of the detected compounds from the February and March sampling rounds with the NJDEP GWQC, and then compares the results with the subsequent site-specific and Monmouth County maximum background levels, where appropriate.

Table 4.3-14
Fort Monmouth - Charles Wood
Summary of Average Concentrations of Detected Compounds in Groundwater - Site CW-9

COMPOUND	METHOD DETECTION LIMIT (µg/L)	NJDEP GROUNDWATER QUALITY CRITERIA (µg/L)	MAXIMUM BACKGROUND CONCENTRATION (µg/L)	ANALYTICAL RESULTS (µg/L) SAMPLING DATE	
				MW35 2/20/95, 3/13/95 (avg.)	MW36 2/20/95, 3/13/95 (avg.)

Sodium	30.5	50000	197000[1]	4480	5900
Vanadium	2.3	NLE	28.9	ND	3.85
Zinc	3.8	5000	133	26.75	27

Compounds exceding NJDEP groundwater quality criteria are noted by bold numbers.

NJDEP groundwater quality criteria consist of the higher number between the PQL or STANDARD

*PQL - Practical Quantitation Limit -was used as the NJDEP groundwater quality criteria

ND - Indicates that the compound was not detected

J - Indicates that the concentration value was estimated due to detection at or near the detection limits

[1] - Monmouth County maximum background concentration.

VOCs

VOCs were not detected in site monitor wells from either sampling round.

SVOCs

SVOCs were not detected above laboratory quantitation limits in site monitor wells from either sampling round.

Pesticides/PCBs

Pesticides/PCBs were not detected in site monitor wells from either sampling round.

Metals

As indicated in Table 4.3-14, of the 15 metals detected in site groundwater, only 3 (aluminum, iron, and magnesium) were found in concentrations exceeding the NJDEP GWQC; however, all three metals were detected in concentrations below the site-specific and Monmouth County maximum background levels.

4.3.9.7 Recommendations

The average concentrations of cadmium and beryllium in surface soil samples at CW-6 and CW-9 do not exceed the NJDEP SCC. Cadmium is typically present at elevated levels at golf courses. No compounds of concern were detected in site groundwater above NJDEP criteria.

No further action will be taken.

Site AOC-7

4.3.10 Former Hazardous Waste Storage Area (AOC-7)

4.3.10.1 Site Location

NJDEP identified this site as an area of concern (AOC) (NJDEP, 1990). A temporary hazardous waste storage area was located in an approximately 1-acre fenced site to the east of Building 2708 (Figure 4.3-16). The site is currently a grassy field surrounded by a 7-ft high fence. A former gas station (Building T-2500) is located to the east of the site. The approximate area of site AOC-7 is 41,000 ft^2 (0.9 acre).

4.3.10.2 Site History

Reviews of aerial photographs from 1961 to 1986 show that this site was a fenced storage area. The 1961 photographs show that the fenced area extended about 50 feet farther to the west than it does today. This western area is now part of the fenced area around Building 2708, which is part of the Pulse Power Laboratory. Large rectangular objects are visible next to the fence on all four sides. These may be cargo or truck vans. The 1969 photograph is similar, but there are three irregular groups of objects at the northwest corner of the lot. The 1974 photograph is similar, except there are five circular igloos along the west fence. In 1986, the site is smaller because the Pulse Power Laboratory is in the western portion of the site. There are objects that appear to be drums along the fence on the south and southeast of the site. The objects are densely packed in a 10- to 20-ft band next to the fence. There are additional objects along the north fence and possibly along the west fence. Personnel interviews indicate that the site was used for a 6-month period in 1987 for temporary storage of hazardous waste (in drums). As part of a program to remove all improperly labeled drums from Fort Monmouth, the facility collected the drums and staged them at this site.

The drums were stored on wood pallets, generally along the fence line. The pallets were not usually stored on a plastic ground cover. Clean Venture, Inc. sampled the drums, labeled them, completed manifests, and arranged for disposal. For the most part, the drums contained solvents, degreasers, and oils. The drums were screened for external radiation and none was detected. Clean Venture did not characterize the drums to the extent of identifying specific compounds,

but some of the solvents that were used at Fort Monmouth at that time are 1,1,2-trichloroethane, 1,1,1-trichloroethane, and benzene.

The only known release of material during the operation occurred on 7 October 1987. A pallet of 5-gallon containers of malathion, a pesticide, was picked up at Sandy Hook. The containers were deteriorated, so the pallet was placed on a plastic ground cover. During the night, the top popped off one of the containers. A security guard became temporarily nauseated from the fumes. The next day the containers were repacked in a drum. The quantity of material that was released is considered small, and it is believed that little, if any, material was spilled on the ground.

4.3.10.3 Sampling Effort

Six soil borings were completed and soil samples collected in an effort to identify the nature and extent of past site activities on soil quality. Soil borings were drilled to groundwater and the soil cuttings were screened with a photoionization detector (PID). Since no elevated PID readings were recorded, soil samples were collected from the interval just above the water table. The total depths of the borings varied from 12 to 14 ft bgs. Lithologic logs from the site borings indicate that the lithology consists of a thin soil cover (0.3 ft) underlain by coarsening downward olive-brown silty medium-grained sand to olive-brown medium-grained sand sequence. The locations of the soil borings were biased toward the fence line, as shown in Figure 4.3-16, because an examination of aerial photographs showed that materials were stored next to the fence. Soil samples were analyzed for TCL +30 parameters and TAL metals.

4.3.10.4 Soil Sampling Results

Six soil samples, one from each boring, were collected from intervals ranging from 8 to 14 ft bgs. Site soil samples were analyzed for the parameters listed in Table 3.6-1. Table 4.3-15 compares the detected compounds in site soil with the NJDEP SCC, and then compares the results with the site-specific and Monmouth County maximum background levels, where

Compounds exceeding NJDEP soil cleanup criteria are noted by bold numbers.
J - Indicates that the concentration value was estimated due to detection at or near the quantification limits
NLE - No Level Established
ND - Indicates that the compound was not detected at or below the quantification limits
[1] Monmouth County maximum background concentrations.
[2] NJDEP criteria are referenced in Site Remediation News, Winter 1995.

appropriate. In addition, the results were compared with the impact to groundwater SCC because no monitor wells were installed at the site.

VOCs

VOCs were not detected above laboratory quantitation limits in site soil.

SVOCs

SVOCs were not detected above laboratory quantitation limits in site soil.

Pesticides/PCBs

One pesticide (4,4'-DDT) was detected above the laboratory quantitation limit in SB-02; however, 4,4'-DDT was detected in a concentration well below both the NJDEP residential direct contact SCCs and impact to groundwater SCC. PCBs were not detected in site soil from any boring location.

Metals

As indicated in Table 4.3-15, all metals detected in site soil were found in concentrations below the NJDEP SCC.

4.3.10.5 Recommendations

No compounds of concern were detected at this site at levels that exceeded NJDEP criteria.

No further action will be taken.

PCB Transformers

4.3.11 PCB Transformers

4.3.11.1 Site Location

During the 1993 investigation (WESTON, 1993), all locations where PCB transformers had formerly been located were inspected for evidence of spills. Three sites were identified where a PCB transformer was either formerly located over soil and thus evidence of a spill could not be determined visually, or formerly located on concrete and there was discoloration in the concrete. These locations are listed in Table 3.5-1 and identified in Figure 4.3-17.

4.3.11.2 Site History

All PCB transformers (contain greater than 500 ppm PCBs) have been removed from Fort Monmouth; however, the former locations of these transformers were not previously investigated for spilled PCBs. The concrete pad outside Building 2000 was removed between the time of the 1993 investigation and the current field effort.

4.3.11.3 Sampling Effort

As discussed in Subsection 3.5, soil samples were taken from below pole-mounted transformers. Because the concrete pad near Building 2000 had been removed, four soil samples were taken downgradient of the former pad location, as indicated in Figure 4.3-18.

4.3.11.4 PCB Sampling Results

The results of the PCB transformer sampling are presented in Table 4.3-16. One of the four transformer sites sampled at the Charles Wood area was found to have PCBs in soil or concrete above NJDEP SCC.

PCBs were detected in four discrete soil samples above NJDEP SCC. The soil samples were collected downslope of the former location of transformer CW035, which was an exterior pad transformer northeast of Building 2000. This pad had been removed prior to sampling.

Table 4.3-16
Results of Transformer Site Sampling on Charles Wood

Location (Building No.)	Sample ID	Method Detection Limt (mg/kg)	Medium	NJDEP Soil Criteria (mg/kg)	Total PCBs (mg/kg)

2276	CWAE-TR01	0.21	Soil	0.49	ND

Compounds exceeding NJDEP cleanup criteria are noted by bold numbers
ND - Indicates that the compound was not detected at the quantification limit.
* = Method Detection Limit exceeded NJDEP criteria.

All other transformers sampled in the Charles Wood area either had results below detection limits, or had detectable levels of PCBs below applicable cleanup criteria.

4.3.11.5 Recommendations

PCBs were detected above the NJDEP criteria in each of the four soil samples collected downgradient of the former transformer location northeast of Building 2000 (transformer CW-035). PCBs were not detected above NJDEP criteria in samples collected from the other three sampling locations.

Additional samples will be taken to further delineate the extent of contamination and the contaminated soil will be removed and disposed of in accordance with applicable regulations. The depth of contamination is assumed to be 6 inches. Excavation will be performed in conjunction with confirmatory soil sampling to ensure that NJDEP SCC are achieved.

SECTION 5
DATA QUALITY

SECTION 5

DATA QUALITY

5.1 INTRODUCTION

Quality assurance/quality control (QA/QC) procedures were incorporated into the Fort Monmouth site investigation program to ensure collection of quality data for each area of the site investigated. Additionally, such QA/QC procedures were employed to ensure that all information, data, and resulting decisions of the site investigation are technically sound, statistically valid (accurate and precise), properly documented, and ensure the completeness of the data. The mechanism for employing the project QA/QC procedures was the CDAP. Procedures in the CDAP facilitated identifying and monitoring the proper sample collection, handling, and laboratory protocols to be used during the site investigation.

Chemical analyses were conducted to determine the type and concentration of contaminants present in the various media at the site and to provide environmental data, as was discussed in Section 2 of this report. Overall, analyses or tests were chosen based on the compounds produced or used within the specific area or the environmental data needed.

The analytical methods that were used for sample analysis are listed in Table 5.1-1. Information on sample containers, preservation, and holding times is presented in Table 5.1-2.

All analytical work completed for the site investigation was performed or administered by WESTON's Environmental Metrics Division. WESTON's Gulf Coast Laboratory, located in University Park, IL, performed all analytical analyses. This laboratory is certified by NJDEP (certification number 54669).

Volatile Organics	Glass, black phenolic plastic screw cap, Teflon-lined septum	40 mL	Cool, 4°C, dark, 0.08% $Na_2S_2O_3$ if residual Cl_2	10 days

TPH - Total Petroleum Hydrocarbons
VTSR - Validated time of sample receipt (at the laboratory)

5.2 QUALITY CONTROL PROCEDURES

To meet the QA/QC objectives of the project, the field work and laboratory analyses followed the standardized methods or procedures that were described in the CDAP and are summarized in the subsections that follow.

5.2.1 Field and Laboratory Quality Control Samples

Standard analytical QC checks instituted by field and laboratory personnel included (but were not limited to):

- Field/rinsate blanks — Samples prepared using analyte-free water supplied by the laboratory or purchased from commercial sources that certify the quality of the water. Field/rinsate blanks were routed through decontaminated sampling equipment prior to collection. Preservatives or additives were added as required, and the blank sample was then sealed. The field/rinsate blank was shipped with real samples collected for the same parameter group. During field sampling, a field/rinsate blank was collected and analyzed from each group of water or soil/solid samples for every 10 samples received daily.

- Trip blanks — Volatile organic sample containers prepared in the laboratory using analyte-free water. The trip blanks accompanied the field samples during transport to the site; during collection, packaging, and transport to the laboratory; and during analysis, and were contained in the same type of sample container as those used in the specific sampling effort. One trip blank sample was included with each shipment of aqueous samples designated for VOC analysis.

- Duplicate samples — Samples collected from the same sampling location at the same time. Soil duplicates were homogenized (with the exception of VOC samples). At least one duplicate sample was analyzed from each group of samples of a similar matrix type for every 20 samples received.

- Matrix spike/matrix spike duplicate (MS/MSD) — Samples in which compounds are added before extraction and analysis. The recoveries for spiked compounds can be used to assess how well the method used for analysis recovers target compounds (i.e., a measure of matrix interference in the sample). When reviewed in conjunction with other QC data, MS/MSDs may indicate reanalysis using a more appropriate method. At least one spiked sample analysis was performed on each group of samples of a similar matrix type and concentration for each batch of samples or for every 20 samples received, whichever was more frequent.

- Surrogate spiking — Samples in which surrogate compounds are added before sample preparation for organics analysis. The review for spiked surrogate compounds can be used to assess method accuracy for each sample matrix.

5.2.2 Field Activities

The accuracy of field measurements obtained from site instruments was maintained on-site by appropriate calibration procedures, as described in detail in the CDAP.

The field investigation procedures used to perform the site investigation were presented in the Fort Monmouth CDAP. The field procedures included:

- Surface and subsurface soil sampling.
- Installation of monitor wells.
- Groundwater sampling.
- Monitor well casing elevation surveying.
- Surface-water and sediment sampling.
- Concrete pad sampling.
- Ancillary field activities, such as decontamination, field measurements, and fluids management.

Sample identification and documentation procedures were followed in the field as specified in the CDAP, including:

- Sample containers were labeled with the appropriate information.
- The sample was entered into the chain-of-custody record.
- A unique sample code was assigned to each sample collected.
- Signed custody seals were applied on opposite sides of the container lid.
- Samples were shipped to WESTON's laboratories as environmental samples and complied with all DOT requirements for such shipment.

A bound field notebook was maintained by the Field Team Leader at the site to record daily activities, including sample collection and tracking information. Quantitative field data, such as water-level measurements, were recorded in bound field notebooks. Qualitative or descriptive field data (such as soil textures) obtained from soil borings and monitor wells were recorded in the field in field notebooks, reduced using a standardized lithologic coding system.

5.2.3 Laboratory Activities

5.2.3.1 Laboratory Equipment Quality Control

The reliability and credibility of laboratory analytical instruments and QA of analytical results were ensured by documented calibration procedures and QC samples (such as method blanks and method spikes). A review of the calibration procedures and the calibration frequencies that are standard operating procedures (SOPs) employed by WESTON's Environmental Metrics Division is provided in the CDAP. The following instruments were used to analyze environmental samples:

- Gas chromatograph (GC).
- Gas chromatograph/mass spectrometer (GC/MS).
- Atomic absorption spectrophotometer: furnace (AA).
- Inductively coupled plasma spectrometer (ICP).
- Cold vapor mercury analyzer: flameless AA.
- Spectrophotometer.

Certain TCL VOCs, such as methylene chloride, acetone, 2-butanone, and toluene, are commonly detected as laboratory contaminants. In order to ensure that the data reported are not biased by potential laboratory contamination, certain QA procedures, including reagent blank analysis, were taken. Assessment of the reagent blanks is discussed in Subsection 5.3.2.

5.2.3.2 Laboratory Data

In addition to the data collected in the field and recorded on the chain-of-custody forms, data describing the processing of samples were accumulated in the laboratory and recorded in laboratory notebooks.

Data reduction was performed by the individual analysts and consisted of calculating concentrations in samples from the raw data obtained from the measuring instruments. The complexity of the data reduction was dependent on the specific analytical method and the number of discrete operations (e.g., extractions, dilutions, and concentrations) involved in obtaining a sample that could be measured.

System reviews were performed at all levels. The individual analyst constantly reviewed the quality of data through calibration checks, QC sample results, and performance evaluation (PE) samples. The Section Manager and/or the Analytical Project Manager reviewed data for consistency and reasonableness with other generated data and to determine if program requirements had been satisfied. Selected hard copy output of data (e.g., chromatograms, spectra, etc.) was reviewed to ensure that results were interpreted correctly. The Quality Assurance Officer independently conducted a review of selected projects to determine if laboratory and client QA/QC requirements had been met. The final routine review was performed by the Laboratory Manager prior to reporting the results to the client.

5.3 DATA QUALITY

5.3.1 Data Reporting

Laboratory reports contain final results, methods of analysis, levels of detection, surrogate recovery data, and method blank data. In addition, special analytical problems and/or any modifications of referenced methods were noted.

5.3.2 Data Validation/Usability Review

Separate from the laboratory's internal data review/data validation, an independent review of the final analytical data packages was performed to validate results and to determine usability. The validation was performed by URS Consultants, Inc. (URS) as a subcontractor to Malcolm Pirnie, Inc.

The data validation was performed in accordance with U.S. Environmental Protection Agency (EPA) *Region II Modifications to the National Functional Guidelines for Organic Data Review, Multimedia, Multiconcentration* (January 1992) and *Region II Modifications to the Laboratory Data Validation Functional Guidelines for Evaluating Inorganic Analysis* (January 1992). For non-CLP procedures, the data were validated following the intent of the National Functional Guidelines.

5.3.3 Results of Data Validation/Usability Review

Malcolm Pirnie issued a Data Validation Report (June 1995) that gave the results of their validation. URS performed data validation services on 84 environmental samples. The matrix type and number of samples were as follows:

Matrix	No. of Samples
Groundwater	33
Surface water	5
Sediment	6
Surface soil	10
Soil boring	24
Transformer soil	4
Concrete	2

URS reported that a majority of the analytical results were usable as reported, despite minor deviations from EPA CLP criteria, which do not jeopardize the chemical representativeness of the data.

There were several instances, however, where compounds or whole fractions were rejected by URS based on deviations from CLP methodologies and/or data validation criteria.

Sample ID	Compound or Fraction
B9-SB01-A02	Acetone
B9-SB01-C02	Acetone
MPA3-SB01-A02	Acetone
MP08-SD01-A01	Semivolatiles, pesticides/PCBs
MP16-SS01-A01	Dieldrin
CW06-SS01-A01	Heptachlor epoxide
MP02-MW01-A01	Total and dissolved aluminum, chromium, and iron

The results for these samples are provided in this report, but are flagged in the Results summary tables. The Data Validation Report includes a discussion of the data quality and completeness.

5.3.4 Results of Field and Trip Blanks

During the Fort Monmouth site investigation, field/rinsate blanks and trip blanks were submitted for analysis (numbers of samples are shown in Tables 5.3-1 and 5.3-2), as discussed in Section 3 of this report. The results of the analyses of the field/rinsate blanks were used to assess the efficiency of the equipment decontamination procedures in preventing cross-contamination between samples, and to determine if the compounds detected in the characterization samples were attributable to the sampling equipment or to the site. The results of trip blank analyses were used to determine if compounds detected in samples analyzed for volatile organics were introduced during shipment or from containers and were not attributable to the site. A discussion of the difference between the samples contracted in the scope of work and the actual effort is included in Section 4.

A summary of the compounds detected in field/rinsate blanks is provided in Table 5.3-3. Inorganics, VOCs, and SVOCs were each detected in at least one field/rinsate blank collected during field activities. All of the organic compounds detected are common laboratory contaminants and were likely introduced into the samples during laboratory analysis.

Note: Numbers in () represent the concentration.
N/A - Not Applicable/No Sample
ND - Not Detected

Additionally, the low contaminant concentrations detected in the field blanks indicate that significant cross-contamination between samples did not occur. VOCs were detected in several of the trip blanks submitted for laboratory analysis. All of the VOCs detected are common laboratory contaminants and, similar to the field/rinsate blanks, were likely introduced into the samples during laboratory analysis. A summary of the analytical results for trip blanks is provided in Table 5.3-3.

5.3.5 Duplicates

Duplicate samples for groundwater, surface water, sediment, and soil were collected following the protocols in the *Site Investigation Fort Monmouth, NJ, Main Post and Charles Wood Areas, Chemical Data Acquisition Plan* (WESTON, December 1994) and are discussed in the subsections that follow. The degree of variation between the sample values (not including values below the quantitation limit) is presented in Table 5.3-4 by media.

5.3.5.1 Groundwater

Of the groundwater duplicate results, 70% were within 10% of the routine sample value and only 16% were not within 20% of the routine sample value. These data indicate reasonable agreement among the groundwater results. Groundwater sample results generally exhibit slight variation due to the homogeneous characteristics of liquid samples.

5.3.5.2 Surface Water

Of the surface-water duplicate results, 63% were within 10% of the routine sample and only 1 sample result was not within 20% of the routine sample. These data indicate reasonable agreement among the surface-water results. Surface-water sample results generally exhibit little variation due to the homogeneous characteristics of liquid samples.

Table 5.3-4
Duplicate Sample Data Within Given Ranges of Percent Variation

Medium	Variation in Duplicate Results										
	0-10	10-20	20-30	30-40	40-50	50-60	60-70	70-80	80-90	90-100	>100
Soil Borings and Surface Soils	31	11	7	4	1	3	7	7	1		3
Sediment	9	7		2							
Surface Water	12	6					1				
Groundwater	106	20	12	5	1	3		1	1	1	1

5.3.5.3 Sediments

Of the sediment duplicate results, 50% were within 10% of the routine sample and only 11% were not within 30% of the routine sample. These data indicate reasonable agreement among the sediment sample results. Sediment sample results tend to show more variation due to the heterogeneity of solid samples.

5.3.5.4 Soils

Of the soil duplicate results, 41% (surface soil and soil boring samples) were within 10% of the routine sample and 35% were not within 30% of the routine sample. These data indicate reasonable agreement among the soil sample results. Soil sample results tend to show more variation, in general, due to the nonhomogeneous nature of solid samples.

5.4 TENTATIVELY IDENTIFIED COMPOUNDS (TICs)

Tentatively identified compounds (TICs) were identified for volatile and semivolatile analyses. The sum of all TICs for every sample is provided in the data tables in Appendix D. In general, the sum of the TICs was small, less than 1 mg/kg for most solids and less than 600 µg/L for water. Significant amounts of TICs occurred in the sediment samples and the soil boring samples. The highest concentration of TICs for any sediment sample was 72 mg/kg, and the highest concentration for any soil sample was 18 mg/kg, both for semivolatile samples. By comparison, the proposed NJDEP cleanup criteria have a limit for total organics of 10,000 mg/kg. The highest concentration of volatile TICs for any solid sample was 1.1 mg/kg. By comparison, the proposed NJDEP limit for total volatile compounds is 1,000 mg/kg. Therefore, the concentration of TICs in solid samples will have no impact on whether it is less than the NJDEP cleanup criteria.

5.5 COMPARISON OF ANALYTICAL DETECTION LIMITS AND REMEDIATION STANDARDS

For certain compounds, the analytical method detection limits exceeded the NJDEP remediation standards. The compounds for which this occurred, along with the most stringent NJDEP remediation standard values and laboratory detection limits, are presented in Table 5.5-1.

The laboratory performed the analysis using the EPA Contract Laboratory Program (CLP) Statement of Work, "Organics Analysis, Multimedia, Multiconcentration," and "Inorganics Analysis, Multimedia, Multiconcentration," for TCL/TAL analyses as specified in the report *Investigation of Suspected Hazardous Waste Sites at Fort Monmouth, New Jersey*, and as approved by NJDEP in a letter dated 20 April 1994. The detection limits are generally in accordance with the method standards.

The detection limits for many surface-water analyses, including VOCs, SVOCs, and pesticides/PCBs, exceeded the most stringent NJDEP criteria. However, additional sampling is proposed at all surface-water sites.

For groundwater, 19 compounds, including VOCs, SVOCs, and pesticides, exceeded the NJDEP criteria. However, additional sampling is proposed for all monitor wells.

Only one compound exceeded NJDEP criteria in soil samples; i.e., toxaphene. Toxaphene was not present in significant quantities in the 1979 inventory of pesticides contained in the IA. Remedial action or additional sampling is proposed for the two pesticide storage areas, i.e., M-16 at the Main Post and CW-6 at Charles Wood.

For sediment, 13 compounds exceeded NJDEP criteria, including SVOCs, pesticides/PCBs, and 2 metals. Because sediment samples were taken at former locations of STP outfalls (STP had not been operating for at least 20 years), metals are the compounds that are of most concern. The detection limit of mercury was generally only slightly above the NJDEP criteria. The detection limit for antimony was generally close to the regulatory limit. Antimony is not believed to have been used in significant quantities at Fort Monmouth because the major activities have been training and research in electronics.

Table 5.5-1
COMPOUNDS FOR WHICH THE ANALYTICAL DETECTION LIMIT EXCEEDS NJDEP REMEDIATION STANDARDS

COMPOUND	NJDEP STANDARD	METHOD DETECTION LIMIT
SURFACE WATER (µg/L)		
1,2-Dichloroethane	0.291	2.4

SECTION 6
CONCLUSIONS AND RECOMMENDATIONS

SECTION 6

CONCLUSIONS AND RECOMMENDATIONS

6.1 MAIN POST

The conclusions and recommendations discussed in the following subsections are for the Main Post area of Fort Monmouth, and are based on the results of the site investigation activities. These conclusions and recommendations are also presented with the site-specific discussions in Section 4 and are summarized in Table 6.1-1.

6.1.1 Landfill 2 (M-2)

Investigation activities performed at site M-2 included the following:

- Sampling of two surface-water locations.
- Installation and sampling of three monitor wells.
- Tidal monitoring.

6.1.1.1 Conclusions

The surface-water sampling results indicate that two VOCs were detected at the two surface-water locations at concentrations greater than NJDEP surface-water criteria, and above maximum background concentrations. In addition, soluble lead was detected at a concentration greater than NJDEP criteria and the maximum background concentrations. Because the site formerly had a New Jersey Pollutant Discharge Elimination System (NJPDES) permit (permit No. 0057274), surface water has been sampled since 1985. The results from the current round of surface-water sampling for VOCs are less than the maximum results from previous rounds.

Chlorobenzene was detected in the groundwater at concentrations exceeding the NJDEP GWQC and background in both downgradient monitor wells from both sampling rounds and in the upgradient well during one sampling round.

Table 6.1-1

Main Post Site Summary and Recommendations

Site	Compounds that Exceed NJDEP Criteria and Maximum Background	Recommendations
M-2 Landfill	Groundwater: Chlorobenzene in 3 wells Surface water: Tetrachloroethene Trichloroethene	Conduct groundwater and surface-water monitoring on a long-term basis.
M-3 Landfill	Groundwater: Chlorobenzene (low value) in 1 well Lead in 1 sample Surface water: None	Conduct groundwater and surface-water monitoring on a long-term basis. Excavate partially exposed drum and conduct confirmatory sampling.
