EXECUTIVE SUMMARY

Versar, Inc. (Versar) is supporting the United States (U.S.) Army Fort Monmouth (Fort Monmouth), Directorate of Public Works (DPW), Monmouth County, New Jersey by preparing a Remedial Investigation Report (RIR) and Remedial Action Workplan (RAW) for the M-2 Landfill. The RIR/RAW is based on work performed by Versar in the summer of 2000, TECOM-Vinnell Services (TVS) in February 1999, and work completed by Roy F. Weston, Inc. (WESTON) in 1995. Versar's evaluation of surface and near-surface soils at the M-2 Landfill site is summarized in a separate RIR entitled, *Remedial Investigation Report for Near-Surface Soils, M-2 Landfill, Draft Report, July 2000*. This report will be submitted under separate cover at a later date.

The M-2 Landfill is located in the southwestern corner of the Main Post area of Fort Monmouth and is approximately 6.5 acres in size. The M-2 Landfill was used between 1964 and 1968 (and possibly into 1969) for general disposal of domestic and industrial wastes (i.e., oil cans, oil burner filters, soot, metal and building rubble). The DPW closed the M-2 Landfill circa 1969. The site is currently stable and supports vegetative growth (i.e., grass, trees, brush), is fenced on three sides, and adjoins Mill Creek to the north.

The M-2 Landfill was first identified as a suspected hazardous waste site at Fort Monmouth in a report prepared by the U.S Army Toxic and Hazardous Materials Agency (USATHAMA) in 1980. WESTON conducted a background investigation on the initially identified sites including the M-2 Landfill and recommended additional investigation. WESTON then performed Site Investigation (SI) activities at the M-2 Landfill. WESTON's findings and recommendations are described in a report entitled, *Site Investigation Report, Fort Monmouth, New Jersey – Main Post and Charles Wood Areas* (December 1995).

Based on the findings of the SI, additional soil and groundwater sampling was performed and a remedial investigation of the landfill was implemented. The following remedial investigation approach was established for the M-2 Landfill:

- Perform a Geoprobe® investigation of the soils and groundwater within the landfill to characterize the near-surface and subsurface soils, the landfill cover materials, and the shallow groundwater to determine whether a source area exists for the volatile organic compounds (VOC) in the groundwater and the stream reported in the SI.
- Install additional groundwater monitoring wells and perform slug and pump tests to determine the aquifer characteristics of the shallow saturated zone beneath the M-2 Landfill. Incorporate the new wells into the quarterly groundwater monitoring program.
- Continue the quarterly surface water sampling. In addition, collect sediment samples at selected locations as well as surface water samples to evaluate potential impact to the stream from the contaminants of concern (COC) detected in the soils and shallow groundwater of the landfill and also to evaluate potential upstream sources of COC.

Sampling of the surface and subsurface soils, groundwater, surface water, and sediment at the M-2 Landfill has delineated the degree and magnitude of potential contaminants. Exceedences of NJDEP Residential Direct Contact Soil Cleanup Criteria (RDCSCC) are identified in the near surface soils for semi-volatile organics (SVOC), pesticides/polychlorinated biphenyls (PCB), and

metals within the landfill. Evaluation of the analytical results did not define a "source area" or level of contamination that necessitated the identification and evaluation of potential remedial actions and no further action is recommended for the near surface soils.

Analyses of deeper soils in the landfill indicated that only PCB in a few scattered locations were detected at concentrations above the RDCSCC. No other compound exceedences were detected in the deeper soils. Sediment and surface water samples were collected from Mill Creek and at locations along the border of the M-2 Landfill to evaluate the potential impact to the stream from the PCB detected in the soils and shallow groundwater of the landfill. PCB were not detected in the sediment or surface water samples above the Lowest Effect Level for PCB listed in the NJDEP's *Guidance for Sediment Quality Evaluations*.

Surface water samples from Mill Creek consistently indicated the presence of PCE and TCE at concentrations slightly above the SWQC of 0.388 micrograms/liter (ug/L) and 1.09 ug/L, respectively. These compounds were not detected in the groundwater beneath the M-2 Landfill. TCE and PCE are presumed to originate from a separate source upgradient of the M-2 Landfill and beyond the boundary of Fort Monmouth.

The findings of the RIR show that shallow groundwater within the defined boundary of the M-2 Landfill exceeds the respective GWQC for benzene and chlorobenzene. These VOC were consistently detected in groundwater samples collected from onsite monitoring wells, but were not detected in Mill Creek, the most significant potential receptor. Some native metal constituents, principally aluminum, iron and manganese, were also elevated, but the detected concentrations are comparable to the Fort Monmouth Maximum Background Concentrations (established for the Main Post during the SI) and regional background conditions.

The DPW is proposing the designation of a Classification Exception Area (CEA) at the M-2 Landfill site. The horizontal and vertical extent of the CEA has been identified by the analysis of existing data to determine the probable maximum extent of future contamination at concentrations above the GWQC. The CEA Proposal includes fate and transport modeling that predicts the future attenuation and migration of contaminants. Based on the analytical data and the fate and transport models used to simulate future conditions, it is predicted that the maximum extent of contamination will never be significantly larger than the current extent of contamination. The CEA Proposal established that a period of 5 to 9 years will be required for the contaminant concentrations to degrade to less than the respective GWQC for benzene and chlorobenzene and further, that benzene and chlorobenzene will not migrate beyond the boundaries of the M-2 Landfill site in the timeframes calculated. Therefore, natural attenuation provides a technically defensible argument for "No Further Action" at the M-2 Landfill. However, the DPW prefers to accelerate the natural attenuation processes and has elected to evaluate several technologies to enhance remediation of the shallow groundwater. The results of this evaluation are presented in a RAW.

The RI findings supported the following remedial action objectives:

- The current institutional controls in place at the M-2 Landfill (i.e., the site is located on an Army-controlled installation and is surrounded on three sides with a six-foot high chain link fence and on the fourth side by Mill Creek) limit direct contact with the site and will be maintained. Periodic inspections of the fencing and landfill cover will be continued.
- Groundwater and surface water monitoring will be continued to demonstrate that contaminant degradation due to natural attenuation is an ongoing process.
- Natural attenuation occurring at the landfill will be enhanced and/or accelerated to more directly mitigate residual levels of benzene and chlorobenzene in the shallow groundwater. While the results of the CEA show that the COC will not migrate beyond the boundaries of the site, nor will the limits of the plume exceed New Jersey GWQC, the DPW has elected to undertake a proactive remedial approach, which is fully presented in the RAW.

The following remedial action alternatives/in-situ remedial technologies were evaluated during preparation of the RAW:

1. Chemical Treatment – Oxygen Release Compound (ORC) and Fenton Reagents;
2. Bioremediation – specifically Enzyme-Enhanced Bioremediation (EEB); and
3. Monitored Natural Attenuation.

The RAW recommends that natural attenuation occurring at the landfill be enhanced through implementation of EEB. The DPW will implement an EEB program over approximately one-half of the overall landfill site specifically targeting six distinct areas where concentrations of benzene and chlorobenzene were detected in the shallow groundwater above the GWQC. EEB will consist of a 2-stage injection of biological enhancements followed by injection of ORC after 30-days to supplement free oxygen. Following a 12-month treatment period, performance sampling will be conducted to evaluate the effectiveness of the remedial action implementation. The results and findings of the proposed remedial action will then be presented in a Remedial Action Report.

To address the PCB concentrations detected in soil at the M-2 Landfill, the DPW will incorporate a document equivalent to a Declaration of Environmental Restriction (DER) into the Fort Monmouth Installation Master Plan for soils containing PCB to restrict site development and future use of the M-2 Landfill site, and formally recognize the planned long-term monitoring of this area. The DPW is the lead agency for all land use issues at Fort Monmouth. A formal DER cannot be established since Fort Monmouth is a Federal facility and, as such, no deed exists.

By submittal of this Report, Fort Monmouth is requesting written approval for Permit-by-Rule for the proposed EEB and ORC application and discharge to groundwater. Fort Monmouth is also requesting approval for the proposed remedial action at the M-2 Landfill and, more specifically, the injection of biological enhancements and ORC. Therefore, an exemption from the requirement to submit a Sanitary Landfill Disruption Application is also requested.

SECTION 1.0
BACKGROUND INFORMATION

1.1 OVERVIEW

Versar, Inc. (Versar) has been contracted by the United States (U.S.) Army Fort Monmouth (Fort Monmouth), Directorate of Public Works (DPW), Monmouth County, New Jersey, to prepare a Remedial Investigation Report (RIR) and Remedial Action Workplan (RAW) for the M-2 Landfill, based on work performed by Versar in the summer of 2000, TECOM-Vinnell Services (TVS) in February 1999, and Roy F. Weston, Inc. (WESTON) in 1995. This report has been prepared in partial fulfillment of Contract No. DACA 51-00-D-004, Delivery Order No.0003.

The report is presented as follows:

Section 1 – Site description, historical information, and physical setting.
Section 2 – Technical overview.
Section 3 – Remedial Investigation Report.
Section 4 – Remedial Action Workplan.
Section 5 – References.

1.2 SITE DESCRIPTION

Fort Monmouth is located in the central-eastern portion of New Jersey in Monmouth County, approximately 45 miles south of New York City and 70 miles northeast of Philadelphia **(Figure 1**). In addition to the Main Post, the installation includes two subposts, the Charles Wood Area and Evans Area. The Main Post encompasses approximately 630 acres and is generally bounded by State Highway 35, Parkers Creek, Lafetra Brook, the New Jersey Transit Railroad, and a residential area to the south. The post was established in 1918 during World War I (WW I) as an Army Signal Corps training center. The Main Post currently provides administrative, training, and housing support functions, as well as providing many of the community facilities for Fort Monmouth. The primary mission of Fort Monmouth is to provide command, administrative, and logistical support for Headquarters, U.S. Army Communications and Electronics Command (CECOM). CECOM is a major subordinate command of the U.S. Army Materiel Command (AMC) and is the host tenant at Fort Monmouth.

The M-2 Landfill, comprised of 6.5 acres, is located on the south bank of Mill Creek in the southwestern corner of the Main Post area. According to a report prepared by the U.S Army Toxic and Hazardous Materials Agency (USATHAMA) entitled, *Installation Assessment of Fort Monmouth, Report 171*, dated May 1980, the M-2 Landfill was in use between 1964 and 1968 (and possibly into 1969) for general disposal of domestic and industrial wastes. The M-2 Landfill has reportedly been inactive since 1969. Since the landfill closure circa 1969, the past 30+ years have seen the growth and stabilization of vegetation (i.e., grass, trees, brush) on the M-2 Landfill. A site map is provided in **Figure 2.**

1.3 HISTORICAL INFORMATION

Suspected hazardous waste sites at Fort Monmouth were initially identified in the Installation Assessment (IA) (USATHAMA, 1980). This report identified 37 sites with known or suspected waste materials at Fort Monmouth. WESTON then conducted a background investigation on these sites and on eight additional sites, identified by Fort Monmouth and the NJDEP. WESTON's Report (WESTON, 1993) recommended additional investigations at 22 of the sites, including the M-2 Landfill, and NJDEP approved the recommendations on 20 April 1994. WESTON performed additional field investigation activities at these 22 sites, including the M-2 Landfill, between November 1994 and November 1995. The field investigation activities included surface geophysical investigations, sediment and surface-water sampling, transformer site sampling, surface and subsurface soil sampling, groundwater monitoring well installation and sampling, and tidal monitoring. The results of these investigation activities were presented in the WESTON Report entitled, *Final Site Investigation, Fort Monmouth, New Jersey, Main Post and Charles Wood Areas, Site Investigation Report*, December 1995.

As stated in the WESTON Report that investigated suspected waste sites at Fort Monmouth (WESTON, 1993) and the Site Investigation (SI) Report (WESTON, 1995), materials generally found in Main Post landfills included unwashed pesticide/herbicide cans, batteries, fluorescent tubes, electronic components, garbage, asbestos wrappings from pipes, soot and boiler scale, sludge from sanitary treatment plants (STPs), small quantities of outdated drugs, outdated photographic chemicals in glass bottles, building rubble (including asbestos-containing materials [ACM]), incinerator ash, sand from oil spill cleanups, and other debris. In addition, specific wastes reportedly known to have been placed in the M-2 Landfill included oil in cans, oil burner filters, and soot. The banks along Mill Creek near the west end of the landfill had also reportedly been covered with building rubble (concrete, cinder blocks, etc.) to stabilize the bank.

1.4 PHYSICAL SETTING

The following is a description of the geological/hydrogeological setting of the area surrounding the M-2 Landfill. Included is a description of the regional geology of the area surrounding Fort Monmouth, as well as descriptions of the local geology and hydrogeology of the Main Post area. A geological map is provided as **Figure 3.**

1.4.1 Geology

Regional Geology

Monmouth County lies within the New Jersey Section of the Atlantic Coastal Plain physiographic province. The M-2 Landfill is located in what may be referred to as the Outer Coastal Plain subprovince, or the Outer Lowlands.
In general, New Jersey Coastal Plain formations consist of a seaward-dipping wedge of unconsolidated deposits of clay, silt, sand and gravel. These formations typically strike northeast-southwest with a dip ranging from 10 to 60 ft (ft) per mile and were deposited on

Precambrian and lower Paleozoic rocks (Zapecza, 1989). These sediments, predominantly derived from deltaic, shallow marine, and continental shelf environments, date from Cretaceous through the Quaternary Periods. The mineralogy ranges from quartz to glauconite.

The formations record several major transgressive/regressive cycles and contain units, which are generally thicker to the southeast and reflect a deeper water environment. More than 20 regional geologic units are present within the sediments of the Coastal Plain. Regressive, upward coarsening deposits are usually aquifers (e.g., Englishtown and Kirkwood Formations, and the Cohansey Sand), while the transgressive deposits act as confining units (e.g., the Merchantville, Marshalltown, and Navesink Formations). The individual thickness for these units varies greatly (i.e., from several ft to several hundred ft). The Coastal Plain deposits thicken to the southeast from the Fall Line (i.e., a boundary zone between older, resistant rocks and younger, softer plain sediments) to greater than 6,500 ft in Cape May County (Brown and Zapecza, 1990).

Local Geology

Based on the regional geologic map (Jablonski, 1968), the Cretaceous age Red Bank and Tinton Sands outcrop at the Main Post area. The Red Bank Sand conformably overlies the Navesink Formation and dips to the southeast at 35 ft per mile. The upper member (Shrewsbury) of the Red Bank Sand is a yellowish-gray to reddish brown clayey, medium-to-coarse-grained sand that contains abundant rock fragments, minor mica and glauconite (Jablonski). The lower member (Sandy Hook) is a dark gray to black, medium-to-fine grained sand with abundant clay, mica, and glauconite.

The Tinton Sand conformably overlies the Red Bank Sand and ranges from a clayey medium to very coarse-grained feldspathic quartz and glauconite sand to a glauconitic coarse sand. The color varies from dark yellowish orange or light brown to moderate brown and from light olive to grayish olive. Glauconite may constitute 60 to 80 percent of the sand fraction in the upper part of the unit (Minard, 1969). The upper part of the Tinton is often highly oxidized and iron oxide encrusted (Minard 1969). Boring and monitoring well logs (**Appendix B**) for the sample borings and monitoring wells installed in the M-2 Landfill give descriptions for the soils at the site to consist of an earthen cover underlain by fill material. Beneath the fill is naturally occurring silty sand. Groundwater occurs beneath the site at a depth of approximately 8 ft. Natural soils beneath the fill are similar to the reported descriptions of the Tinton Sand member of the Red Band Sand.

The Kirkwood Formation (part of the Kirkwood-Cohansey system) crops out southeast of the Main Post and dips to the southeast at a slope of 20 ft per mile (Jablonski, 1968). The Kirkwood Formation consists of alternating layers of sand and clay. The upper unit is a light gray to yellowish-brown, fine-grained quartz sand with quartz nodules and small pebbles. The lower unit is a brown silt in Monmouth County (Jablonski, 1968).

1.4.2 Soils

According to the U.S. Department of Agriculture (USDA), Soil Conservation Service, Monmouth County Soil Survey, the majority of the Main Post is covered by urban land. The soil

survey described urban land as areas where concrete, asphalt, buildings, shopping centers, airports, or other impervious surfaces cover 80 percent or more of the surface. In addition, the survey indicated that the natural subsurface soils have largely been replaced with artificial or foreign fill materials (developed land with disturbed soils). The following soil series and classification units are mapped in the Main Post area:

- DoB Downer sandy loam (with 2 to 5 percent slopes);
- FrB Freehold sandy loam (with 2 to 5 percent slopes);
- FUB Freehold sandy loam/urban land complex (with 0 to 10 percent slopes);
- HV Humaquepts, frequently flooded;
- KvA Kresson loam (with 0 to 5 percent slopes);
- UA Udorthents, smoothed; and
- UD Udorthents – urban land complex (with 0 to 3 percent slopes).

The Downer series soils are well-drained soils that are found on uplands and terraces. The soils are formed in acid, silty coastal plain sediments. The Freehold soils are also well drained and are formed in acid, loamy, coastal plain sediments that, by volume, are 1 to 10 percent glauconite and are found on uplands. The Humaquepts soils are somewhat poorly- to very poorly- drained soils that are formed in stratified, sandy, or loamy sediments of fluvial origins. The Humaquepts soils are located on the floodplain and are subject to flooding several times each year. The Kresson loam is a nearly level to gently sloping soil and is somewhat poorly drained. The soil is found on low divides and in depressions. The Udorthents soils have been altered by excavation or filling activities. In filled areas, these soils consist of loamy material that is more than 20 inches thick. The filled areas include floodplain, tidal marshes, and areas with moderately, well drained to very poorly drained soils. Some Udorthent soils contain concrete, asphalt, metal, and glass.

1.4.3 Hydrogeology

Regional Hydrogeology

Fort Monmouth lies in the Atlantic and Eastern Gulf Coastal Plain groundwater region (Meisler et al., 1988). This groundwater region is underlain by undeformed, unconsolidated to semi-consolidated sedimentary deposits. The chemistry of the water near the surface is variable with low dissolved solids and high iron concentrations. The water chemistry in areas underlain by glauconitic sediments (such as Red Bank and Tinton Sands) is dominated by calcium, magnesium, and iron. The sediments in the area of Fort Monmouth were deposited in fluvia-deltaic to nearshore environments.

The water table aquifer in the Main Post area is identified as part of the "composite confining units," or minor aquifers. The minor aquifers include the Navesink formation, Red Bank Sand, Tinton Sand, Hornerstown Sand, Vincentown Formation, Manasquan Formation, Shark River Formation, Piney Point Formation, and the basal clay of the Kirkwood Formation.

Well records indicate that wells installed in the Red Bank and Tinton Sands produce 2 to 25 gallons per minute (gpm). Water in these upper hydrogeologic units is typically encountered at shallow depths below ground surface (2 to 9 ft bgs). However, domestic wells are generally screened deeper in these upper hydrogeologic units. The shallow water table conditions in the Tinton and Red Bank Sands, and the similar composition of these sands within the Kirkwood Formation, suggest that the Tinton-Red Bank-Kirkwood sequence forms a single, laterally continuous aquifer. Water in this water table aquifer will flow east toward the Atlantic Ocean. Local topography will tend to deflect the flow toward local depressions.

As stated in the SI Report (WESTON, 1995), NJAC 7:9-6, *Groundwater Quality Standards,* establishes groundwater criteria for different classes of groundwater. Class II-A, which is defined as all groundwater that is not classified as one of the other special classes, is the class for groundwater at Fort Monmouth. The primary designated use for Class II-A groundwater is potable water; secondary uses include agricultural and industrial water.

Local Hydrogeology

Shallow groundwater is locally influenced within the Main Post area by the following factors:

- Tidal influence (based on proximity to the Atlantic Ocean, rivers, and tributaries)
- Topography
- Nature of the fill material within the Main Post area
- Presence of clay and silt lenses in the natural overburden deposits
- Local groundwater recharge areas (i.e., streams, lakes)

Due to the fluvial nature of the overburden deposits (i.e., sand and clay lenses), shallow groundwater flow direction is best determined on a case-by-case basis. The groundwater flow in the vicinity of the M-2 Landfill has been determined to be north-northwest towards Mill Creek.

1.4.4 Topography

Over the last 80 years, the natural topography of Fort Monmouth has been altered by excavation and filling activities by the military. The land surface at the Main Post is relatively flat and ranges in elevation from 4 ft above mean sea level (msl) in the east at Oceanport Creek to 32 ft msl at the western end of the post, near Highway 35. The eastern half of the post is generally 10 ft msl in elevation.

1.4.5 Surface Water and Wetlands

Surface water runoff from the western part of the Main Post flows into the Lafetra Creek to the north or into the Mill Creek to the south. The USGS map (**Figure 1**) shows the Lafetra Creek as Parkers Creek Branch and Mill Creek as Wampum. Both Mill and Lafetra Creek originate off-post. Mill Creek flows along the southern boundary of the Main Post, turning north just past the Auto Craft Shop. Mill Creek is channelized and flows past the north side of the M-2 Landfill. Lafetra Creek forms the northern boundary of the Main Post and joins Mill Creek to form Parkers Creek. Parkers Creek flows eastward along the northern boundary and joins Oceanport Creek east of the post. Most of Parkers Creek, Lafetra Creek, and Mill Creek are tidally influenced.

The U.S Fish and Wildlife Service (FWS) National Wetland Inventory Long Branch quadrangle maps indicate the presence of wetlands at the Main Post. Parkers and Oceanport Creeks are classified as estuarine intertidal aquatic beds. The area of Parkers Creek and the part of Oceanport Creek/Husky Brook are classified as estuarine intertidal emergent wetlands. Lafetra Creek and Mill Creek are classified as riverine lower perennial open water/unknown bottom.

SECTION 2.0
TECHNICAL OVERVIEW

2.1 SITE INVESTIGATION SUMMARY

The investigation activities performed by WESTON at the M-2 Landfill in support of the SI included sampling of two surface-water locations, installation and sampling of three monitoring wells (MW-1, MW-2, and MW-3), and tidal monitoring. Two rounds of groundwater samples and one round of surface-water samples were collected and analyzed for Target Compound List (TCL) + 30 parameters (which include volatile organic compounds (VOC), semi-volatile organic compounds (SVOC), pesticides, polychlorinated biphenyls (PCB)), Target Analyte List (TAL) metals, and cyanide.

In addition, during performance of the SI, a total of ten groundwater and soil background samples and two sediment and surface water samples were taken on both Charles Wood and the Main Post. Maximum background concentrations were then established and reported in the SI for soil, groundwater, surface water, and sediment at the Main Post and Charles Wood Areas at Fort Monmouth for use in evaluating the analytical results from the SI (Tables 4.1-6 through 4.1-9, WESTON, 1995). (NOTE: References in this Report to maximum background concentrations refer to the Fort Monmouth – Main Post Maximum Background Concentrations presented in the SI Report, WESTON, 1995).

The SI findings of groundwater and surface water sampling were as follows:

<u>Groundwater</u>

Chlorobenzene (CB) was the only VOC detected in the groundwater at the M-2 Landfill. CB was detected at concentrations exceeding the NJDEP GWQC from both sampling rounds in MW-2 and MW-3. CB was not detected in the first sampling round in MW-1, but was detected in the second sampling round in exceedence of the NJDEP GWQC.

SVOC, pesticides, and cyanide were not detected above the laboratory quantitation limits in either sampling round.

Twenty metals were detected in site groundwater, however, only five (aluminum, arsenic, iron, manganese, and lead) were found at concentrations exceeding the NJDEP GWQC. However, for the most part, the five metals were found at concentrations below maximum background concentrations.

The table below summarizes the analytical results from the SI of the samples and averaged concentrations of compounds detected above both the New Jersey GWQC and maximum background concentrations.

Monitoring Well Analytical Data Summary Table - 1995

Compound	NJDEP Groundwater Criteria	Site Background Concentrations	Analytical Results (ug/L) 2/15/95, 3/8/95		
			MW-1 (avg.)	MW-2 (avg.)	MW-3 (avg.)
VOC (ug/L)					
Chlorobenzene	4	ND	**17.5**	**29**	**10**
Metals (ug/L)					
Aluminum	200	121000	**5355R**	**2061.5**	**1616.5**
Arsenic	8	89.3	**8.95**	--	--
Iron	300	431000	**15900**	**61250**	**20450**
Manganese	50	331	**78.55**	**286.5**	**483.5****
Lead	10	22.7	--	**11.55***	**14.8**

Source: WESTON, 1995
ug/L - micrograms/liter
* **11.55 ug/L –** New Jersey GWQC exceedence
** **483.5 ug/L** – Background exceedence

Surface Water

Tetrachloroethene (PCE) and trichloroethene (TCE) were the only VOC detected. They were both detected at locations SW-1 and SW-2 at concentrations in the unfiltered samples greater than the NJDEP freshwater criteria and maximum background concentrations.

Bis(2-ethylhexyl) phthalate was the only SVOC detected and at a concentration greater than the NJDEP freshwater criteria and maximum background concentrations at location SW-2, but this detection was considered attributable to sampling or laboratory contamination.

Pesticides and PCB were not detected in the surface water samples.

Of the 13 metals detected in the surface water samples, only the filtered lead sample was found at a concentration greater than the NJDEP freshwater criteria and maximum background concentration.

The table below summarizes the analytical data for the stream and sediment sampling performed during the SI.

Stream & Sediment Analytical Data Summary Table - 1994

Compound	NJDEP Freshwater Criteria	Site Maximum Background (total)	Site Background (soluble)	Analytical Results (ug/L) 12/1/94			
				M-2 (total)		M-2 (soluble)	
				SW-1	SW-2	SW-1	SW-2
VOC							
Tetrachloroethene	0.388	ND	ND	**5J**	**5J**	NA	NA

During performance of the SI activities, groundwater saturation was observed at approximately 8 ft below ground surface (bgs), and water elevation data indicated that local groundwater flow was north toward Mill Creek. Based on observed groundwater elevation measurements, MW-1 was determined to be upgradient and monitoring wells MW-2 and MW-3 were determined to be downgradient of the M-2 Landfill. In addition, based on conductivity and salinity data and field observations, both surface water sampling locations were determined to be freshwater.

Results of the tidal monitoring indicated that there was no apparent relationship between the changing creek water levels and observed water levels in the upgradient monitoring well (MW-1); however, a direct relationship was observed between changing creek water levels and the observed water levels in the downgradient monitoring wells (MW-2 and MW-3).

The SI Report stated that, although New Jersey GWQC criteria had been exceeded for one VOC and surface water results were slightly exceeded by two VOC, an immediate remedial action was not required for several reasons:

1. Immediate remedial action is usually based on an immediate threat to human health. Based on the findings of the SI, the groundwater and surface waters at the M-2 Landfill were not used for drinking water, so human health impacts were not likely.
2. Surface water sampling had been performed at the M-2 Landfill since 1986, and since the landfill had not been used for decades, the concentrations of VOC were perceived, at worst, to be stable and possibly decreasing.
3. Presumably, since no material was being added to the source (i.e., the landfill), natural degradation would decrease groundwater and surface-water contamination levels in the future.

4. Previous surface water sampling at the M-8 Landfill had indicated that NJDEP surface-water criteria had not been exceeded for VOC. Therefore, the only portion of Mill Creek for which NJDEP surface water criteria had been exceeded was the portion between the M-2 and the M-8 Landfills, which resides on Fort Monmouth and is maintained under restricted access.

The SI Report also presented a DPW proposal for the M-2 Landfill site that was subsequently implemented. Because the existing monitoring wells and surface water sampling locations were adequately spaced to monitor downgradient groundwater and surface water conditions, a long-term surface water and groundwater monitoring program was developed.

Following completion of the SI, Fort Monmouth committed to implementing the long-term groundwater monitoring program and intended to submit a RAW to NJDEP recommending natural attenuation at the M-2 Landfill. However, based on the results of initial groundwater sampling and a request by NJDEP for further groundwater characterization, an "enhanced" SI for groundwater was conducted. The enhanced SI identified benzene and PCB in the groundwater at the M-2 Landfill. This resulted in the performance of a remedial investigation (RI) encompassing soil and groundwater characterization to determine the extent of the PCB and benzene impacts at the M-2 Landfill Site.

2.2 RELIABILITY AND QUALITY OF LABORATORY ANALYTICAL DATA

Soil and water chemical analyses for the samples collected at the M-2 Landfill were conducted at the Fort Monmouth Environmental Testing Laboratory, a New Jersey certified laboratory (Certification No. 13461). Review of the analytical data report packages provided by the laboratory indicated that analytical data is of good quality and is reliable. A summary of the analysis parameters and analytical methods used by the laboratory is provided below.

Summary of Analytical Methodology

Analysis Parameter	EPA Method
Volatile Organic Compounds (VOC) – Aqueous	624
Volatile Organic Compounds (VOC) - Soil	8260
Semi-Volatile Organic Compounds (SVOC)	625
Pesticides/PCB in Soil	8082
Pesticides/PCB in Water	608
ICP TAL Metals	3120B
Mercury	3112B

The data reports indicate that the appropriate analytical methods were used, holding times were met, and duplicate and blank analyses showed good reproducibility. The method detection limits achieved by the laboratory for the various analytes were well below the regulatory limits.

2.3 SIGNIFICANT EVENTS/SEASONAL VARIATION

Surface water in Mill Creek has been sampled monthly and then quarterly from October 1996 through June 2000. Groundwater has been sampled quarterly since May 1997. During this period, the only significant events were the drought of the summer of 1998 and Hurricane Floyd in September 1999. These events did not influence sampling procedures, and evaluation of the reported analytical results for the surface and groundwater samples showed no discernable effect on analyte concentrations. Similarly, the analytical results show no discernable seasonal variation.

2.4 TREATABILITY, BENCH-SCALE AND PILOT-SCALE STUDIES

There were no treatability, bench-scale or pilot-scale studies required in support of the Remedial Investigation for the M-2 Landfill.

2.5 DEVELOPMENT OF PERMIT LIMITATIONS

Data has not been collected, to date, to develop permit limitations in support of the proposed remedial actions for the M-2 Landfill.

2.6 ECOLOGICAL ASSESSMENT SUMMARY

Ecological assessments were not done as part of the Remedial Investigation of the M-2 Landfill.

SECTION 3.0
REMEDIAL INVESTIGATION

3.1 REMEDIAL INVESTIGATION APPROACH

The primary findings of the SI for the M-2 Landfill were as follows:

- In the groundwater, CB was detected at concentrations exceeding the New Jersey GWQC and the maximum background concentrations in both downgradient monitoring wells (MW-2 and MW-3) during both sampling rounds, and in the upgradient well (MW-1) during one sampling round.

- In the surface water, PCE and TCE were both detected in the unfiltered surface water samples at concentrations greater than the NJDEP freshwater criteria and maximum background concentrations at locations SW-1 and SW-2. Only the filtered lead sample was found at a concentration greater than the NJDEP freshwater criteria and maximum background.

- Based on the results of tidal monitoring performed during the SI, there appeared to be no apparent connection between the creek and the upgradient monitoring well (MW-1); however, a direct relationship was observed between the creek and the downgradient monitoring wells (MW-2 and MW-3).

The findings of the SI established a preliminary conceptual model for the site:

- Air. Upon closure, the landfilled area had been leveled and graded with cover material. There was no evidence of any potential impacts to the environment via the air pathway.

- Soils. The landfill had been inactive since approximately 1968 and the past 30+ years had seen the growth and stabilization of vegetation (i.e., grass, trees, brush) on the landfill. However, the exact nature of the cover materials was uncertain. In addition, no soil samples had been collected from the landfill during the SI. A source area might exist within the fill material that was impacting the shallow groundwater and/or surface water.

- Groundwater. VOC (chlorobenzene) had been detected in both the upgradient and downgradient wells. Since CB had not been detected in the surface water samples, the landfill appeared to be impacting the shallow groundwater. In addition, there appeared to be a connection between the shallow groundwater at the site in the downgradient monitoring wells and the stream.

- Surface Water. PCE and TCE were both detected in the unfiltered surface water samples at both sampling locations. However, the results of the long-term Fort Monmouth

surface water sampling program showed that there is an upgradient source of the VOC in Mill Creek located beyond the boundary of Fort Monmouth.

The following remedial investigation approach was established:

- Perform a Geoprobe® investigation of the soils and groundwater within the landfill to characterize the near-surface and subsurface soils, the landfill cover materials, as well as the shallow groundwater to determine whether a source area exists for the VOC observed in the groundwater and the stream.

- Install additional groundwater monitoring wells both within and below the landfilled materials and perform slug and pump tests to determine the aquifer characteristics of the shallow saturated zone beneath the M-2 Landfill. Incorporate the new wells into the quarterly groundwater monitoring program.

- Continue the quarterly surface water sampling. In addition, collect sediment samples at selected locations as well as surface water samples to evaluate potential impact to the stream from the contaminants of concern (COC) detected in the soils and shallow groundwater of the landfill and also to evaluate potential upstream sources of COC (i.e., PCE and TCE).

3.2 REMEDIAL INVESTIGATION ACTIVITIES

Based on the results and findings of the SI and the established remedial investigation approach, a complete RI was initiated during February 1999. Remedial investigation activities were managed by the DPW and implemented by TVS personnel and Versar. All analyses were performed and reported by the Fort Monmouth Environmental Testing Laboratory, an NJDEP-certified testing laboratory. All sampling was performed in accordance with the methods described in the NJDEP *Field Sampling Procedures Manual.* Sampling frequency and parameters analyzed complied with the NJDEP *Technical Requirements for Site Remediation* (N.J.A.C. 7:26E). Fort Monmouth Standard Operating Procedures (SOPs) for the performance of GeoProbe® investigations, PCB, and groundwater sampling are provided in **Appendix A.** Analytical results were first compared to the respective method detection limit (MDL) and maximum background concentration (where applicable and appropriate). Analytical results that exceeded the MDL and the maximum background concentration (where applicable and appropriate) were then compared to the respective NJDEP criteria.

3.2.1 PCB Investigation

In February 1999, a GeoProbe® soil and groundwater investigation was conducted to delineate PCB concentrations, both horizontally and vertically. Samples were collected along an established grid at alternating 6-inch intervals from the surface to the observed water table. At locations where PCB concentrations were detected at the RDCSCC for PCB of 0.49 milligrams/Kilogram (mg/Kg) or greater, another sample was collected 0.5 ft deeper at that same location. This process continued until concentrations less than 0.49 mg/Kg were detected.

When PCB concentrations in the samples collected at a grid location exceeded 0.49 mg/Kg, another surface sample was collected at the next location further along the established grid. This method continued until observed PCB concentrations were less than the RDCSCC.

Soil Investigation

As part of the PCB soil investigation, 73 GeoProbe® soil borings were advanced from two areas within the M-2 Landfill site. One area was located in the eastern portion of the landfill in the vicinity of MW-23 and the second in the western portion of the landfill in the vicinity of MW-02. A total of 622 soil samples (and 25 duplicate samples) were collected and analyzed for Total PCB using EPA Method 8082. Analytical results were reported for the following PCB Arochlors: 1016, 1221, 1232, 1242, 1248, 1254, and 1260. The analytical results for the PCB Arochlors detected above the MDL in each soil sample are presented in **Table 1**. The analytical results for the PCB Arochlors reported above the respective MDL for each soil sample have also been summed in **Table 1** to establish a Total PCB value for that sample. The analytical results for each sample and each Arochlor (as well as the calculated Total PCB value) detected above the RDCSCC for PCB of 0.49 mg/Kg have then been **bolded** in **Table 1**.

PCB were detected above the MDL in 51 of the soil borings and at concentrations that exceeded the RDSCC of 0.49 mg/Kg at 40 boring locations and in 82 of the samples. The PCB detected were primarily Arochlors 1016 and Arochlor 1260, although Arochlors 1242 and 1254 were also occasionally detected. The PCB concentrations greater than the RDCSCC ranged from 0.496 mg/Kg to 805.06 mg/Kg. The PCB were detected at depths that ranged from 0.5 to 8.5 ft bgs and appeared to be randomly distributed both within and among the borings. In most cases, if a detection for PCB was reported in a soil boring, the next sample depth interval was either non-detect (ND) or below the RDCSCC and representative of isolated detections by depth. No specific source area for the PCB in the soil was defined. Additionally, the reported elevated PCB concentrations are proximate to monitoring wells MW-6 and MW-9. These monitoring wells had exceedences of the GWQC for PCB during several sampling events in 1998 and early 1999 conducted as part of the Fort Monmouth Quarterly Groundwater Monitoring Program. No PCB exceedences have been observed in monitoring wells MW-6 and MW-9 since July 1999. The boring locations and the calculated Total PCB value for each boring and sample depth are shown in **Figure 4 (Sheets 1 and 2).** In addition, Total PCB values detected above the RDCSCC for PCB have been "boxed" in "red".

Groundwater Investigation

Groundwater samples were collected from 45 of the soil borings from both areas (i.e., in the vicinity of MW-23 and MW-02) and submitted for Total PCB analysis. Analytical results were reported for the following PCB Arochlors: 1016, 1221, 1232, 1242, 1248, 1254, and 1260. The analytical results for the PCB Arochlors detected above the MDL in each groundwater sample are presented in **Table 2**. The analytical results for the PCB Arochlors reported above the respective MDL for each groundwater sample have also been summed in **Table 2** to establish a Total PCB value for that sample. The analytical results for each sample and each Arochlor (as

well as the calculated Total PCB value) detected above the GWQC for PCB of 0.50 micrograms/liter (ug/L) have then been **bolded** in **Table 2**.

PCB were detected in the groundwater samples collected from 14 boring locations. The groundwater samples collected from eight (of the 14) boring locations also exceeded the NJDEP GWQC for PCB of 0.50 ug/L. The boring locations and the calculated Total PCB value for each boring and sample depth are shown in **Figure 5.** In addition, Total PCB values detected above the GWQC for PCB have been "boxed" in "red". Two of the groundwater samples with PCB above the GWQC were located within the "eastern" sampling area (i.e., in the vicinity of MW-23): Boring Locations 21 and 23. Six of the groundwater samples with PCB above the GWQC were located within the "western" sampling area (i.e., in the vicinity of MW-02): Boring Locations 1, 4, 9, 9A, 9B, and 15B. In collecting the groundwater samples as "grab samples" from the installed borings, sediments containing PCB were likely entrained within the groundwater samples, thereby impacting the reported results.

In comparison to the results of the soil investigation presented in **Table 1** and on **Figure 4**, Boring Location 21 presented two detections of PCB, with one detection (22.396 mg/Kg) above the RDCSCC. Boring Location 23 contained one detection for PCB (0.914 mg/Kg) that was also above the RDCSCC. However, a total of 13 borings within the "eastern" area contained soil samples with detections of PCB greater than the RDCSCC. This was not represented in the findings of the groundwater investigation, confirming the lack of a defined source area for the PCB within that area. Within the "western" sampling area:

- Boring Location 1 contained five detections of PCB with two detections (9.806 and 3.206 mg/Kg) exceeding the RDCSCC;
- Boring Location 4 contained two detections (4.498 and 75. 833 mg/Kg) of PCB that also exceeded the RDCSCC;
- Boring Location 9 contained one detection of PCB (0.696 mg/Kg) that also exceeded the RDCSCC;
- Boring Location 9A contained three detections of PCB that did not exceed the RDCSCC;
- Boring Location 9B had no detections of PCB, and
- Boring Location 15B had no detections of PCB.

A total of 26 boring locations within the "western" sampling area contained soil samples with detections greater than the RDCSCC. While some consistency was shown between the soil and groundwater samples collected at Boring Locations 1, 4, 9, and 9A, there was still no confirmation of a defined source area for the PCB. Further, PCB have not been detected at MW-02 or MW-23 in sampling conducted as part of the Fort Monmouth Quarterly Groundwater Monitoring Program.

Given the likely random nature and placement of waste materials within the M-2 Landfill, the findings of the soil and groundwater investigation for PCB are consistent with the lack of a defined source area and illustrate the variety of waste materials placed within the landfill. Furthermore, because the groundwater investigation was performed primarily using a GeoProbe®

approach, the sediment concentration and turbidity of the collected groundwater samples likely increased the number of PCB detections at the site.

3.2.2 Benzene/Chlorobenzene Investigation

In March 1999, following the PCB investigation, a soil investigation was conducted to delineate benzene and CB concentrations in both the soil and shallow groundwater of the M-2 Landfill.

Soil/Fill Investigation

A total of 208 GeoProbe® soil samples were collected during the soil/fill investigation at varying depths ranging from 12-inches to 108-inches bgs. The intent of the sampling was to obtain a complete soil column from 0-6 inches bgs to the observed water table. A 4-ft split-spoon soil sample was obtained and screened visually and by using a photoionization detector (PID)/FID. If any contamination was observed, a sample was collected. If nothing was visually observed or detected by the field-screening instrument, a sample was still taken just above the water table. The collected samples were submitted for VOC analysis using EPA Method 8260. **Table 3** summarizes the analytical results for the detected VOC and **Figure 6** shows the boring locations and the analytical results for benzene and CB as well as the respective sample depth. In addition, benzene and CB detections above the respective RDCSCC have been **bolded** on **Table 3** and "boxed" in "red" on **Figure 6**.

Ten (10) VOC were detected in the collected soil samples: methylene chloride, carbon disulfide, CB, benzene, ethyl-benzene, total xylenes, 2-butanone, toluene, acetone, and chloroform. Methylene chloride was detected in 34 samples ranging from 0.64 mg/Kg to 5.0 mg/Kg, with no detections above the RDCSCC of 49 mg/Kg. Carbon disulfide was detected in two samples at 0.99 and 1.5 mg/Kg (there is no RDCSCC for carbon disulfide). CB was detected in 17 samples ranging from 0.43 mg/Kg to 6.0 mg/Kg, with no detections above the RDCSCC of 37 mg/Kg. Benzene was detected in six samples ranging from 0.34 mg/Kg to 0.68 mg/Kg, with no detections above the RDCSCC of 3 mg/Kg. Ethylbenzene was detected in one sample at 1.1 mg/Kg, which is below the RDCSCC of 1000 mg/Kg. Xylene (as total xylenes) was detected in four samples ranging from 0.55 mg/Kg to 4.0 mg/Kg, with no detections above the RDCSCC of 410 mg/Kg. 2-Butanone was detected in 47 samples ranging from 0.97 mg/Kg to 7.6 mg/Kg, with no detections above the RDCSCC of 1000 mg/Kg. Toluene was detected in three samples ranging from 0.42 mg/Kg to 2.0 mg/Kg, with no detections above the RDCSCC of 1000 mg/Kg. Acetone was detected in 40 samples ranging from 1.7 mg/Kg to 10.0 mg/Kg, with no detections above the RDCSCC of 1000 mg/Kg. Chloroform was detected in 71 samples ranging from 0.29 mg/Kg to 2.5 mg/Kg, with no detections above the RDCSCC of 19 mg/Kg.

In summary, while there were detections of VOC in the shallow subsurface soils (to a depth of approximately 7-8 ft bgs), no VOC and specifically benzene and CB, were found to exceed the respective NJDEP RDCSCC.

Groundwater Investigation

The groundwater investigation was conducted in conjunction with the soil/fill investigation. Groundwater samples were collected from each of the 185 GeoProbe® borings following the soil sample collection. The collected samples were submitted for VOC analysis using EPA Method 624.

Table 4 summarizes the analytical results for the detected VOC and **Figure 7** shows the boring locations and the analytical results for benzene and CB as well as the respective sample depth. In addition, benzene and CB detections above the respective GWQC have been **bolded** on **Table 4** and "boxed" in "red" on **Figure 7**.

A total of twenty (20) VOC were detected in the collected groundwater samples: methylene chloride, carbon disulfide, CB, benzene, ethyl-benzene, total xylenes, toluene, acetone, chloroform, 1,4-dichlorobenzene (DCB), 1,2-DCB, 1,3-DCB, PCE, TCE, vinyl chloride (VC), trans-1,2-dichloroethane (DCE), 2-butanone, tert-butyl alcohol, and methyl-tert-butyl ether. Methylene chloride was not detected in any of the collected groundwater samples, but was detected in six of the collected field blank samples ranging from 2.35 ug/L to 5.0 ug/L, with all six detections exceeding the GWQC of 2 ug/L. Carbon disulfide was detected in 31 of the collected groundwater samples ranging from 1.10 ug/L to 20.61 ug/L (there is no established GWQC for carbon disulfide). CB was detected in 148 of the collected groundwater samples ranging from 1.00 ug/L to 181.39 ug/L, with 125 of the detections exceeding the GWQC of 4 ug/L. Benzene was detected in 100 of the collected groundwater samples ranging from 0.55 ug/L to 14.67 ug/L, with 98 of the detections exceeding the GWQC of 1 ug/L. Ethyl-benzene was detected in three of the collected groundwater samples ranging from 1.12 ug/L to 3.15 ug/L, with none of the detections exceeding the GWQC of 700 ug/L. Xylene (as total xylenes) was detected in ten of the collected groundwater samples ranging from 1.39 ug/L to 7.82 ug/L, with none of the detections exceeding the GWQC for total xylene of 40 ug/L. Toluene was detected in ten of the collected groundwater samples ranging from 1.06 ug/L to 5.65 ug/L, with none of the detections exceeding the GWQC of 1000 ug/L. Acetone was detected in 37 of the collected groundwater samples ranging from 1.95 ug/L to 53.79 ug/L and in two of the collected field blanks, none of the detections exceeded the GWQC for acetone of 700 ug/L. Chloroform was detected in four of the collected groundwater samples ranging from 1.32 ug/L to 26.80 ug/L and in four of the collected field blanks. Two of the groundwater detections for chloroform exceeded the GWQC of 6 ug/L. The two detections were associated with Boring Location 115B and a field duplicate collected from that sample (26.80 ug/L and 26.06 ug/L, respectively). 1,4-DCB was detected in 132 of the collected groundwater samples ranging from 1.01 ug/L to 17.96 ug/L, with none of the detections exceeding the GWQC of 75 ug/L. 1,2-DCB was detected in 15 of the collected groundwater samples ranging from 0.93 ug/L to 2.51 ug/L, with none of the detections exceeding the GWQC of 600 ug/L. 1,3-DCB was detected in 28 of the collected groundwater samples ranging from 0.84 ug/L to 4.87 ug/L, with none of the detections exceeding the GWQC of 600 ug/L. PCE, TCE, VC, trans-1,2-DCE, and cis-1,2-DCE were all detected only once in the groundwater sample collected from boring location No. 48. The PCE, TCE, VC, and cis-1,2-DCE detections all exceeded the respective GWQC: 6.51 ug/L vs. 1 ug/L; 16.71 ug/L vs. 1 ug/L; 15.75 ug/L vs. 5 ug/L, and 72.00 ug/L vs. 10 ug/L, respectively. 2-Butanone was detected in five of the collected groundwater samples ranging from 2.46 ug/L to 186.75 ug/L, with none of the detections exceeding the GWQC of 1000 ug/L. Tert-Butyl alcohol was detected

in three of the collected groundwater samples ranging from 53.08 ug/L to 91.11 ug/L (there is no established GWQC for tert-butyl alcohol). Methyl-tert-Butyl ether was detected in two of the collected groundwater samples at 2.31 ug/L and 3.04 ug/L (there is no established GWQC for methyl-tert-butyl ether).

In summary, there were a number of relatively minor detections of VOC in the groundwater samples collected from the installed boring locations. Detections for CB, benzene, PCE, TCE, VC, and cis-1,2-DCE exceeded the respective GWQC. In the case of PCE, TCE, VC, and cis-1,2-DCE, there was only a single detection for each of these VOC at one boring location (No. 48). There were no VOC detected in the soil sample collected from Boring Location No. 48. The chlorinated hydrocarbons (i.e., PCE, TCE, DCE, and VC) are not areally extensive and do not warrant further investigation or active remediation based on the probable land and water uses at Fort Monmouth. They will be addressed incidentally with the implementation of the remedial strategy presented herein.

Based on the groundwater sampling results, benzene and CB are present in the shallow groundwater beneath the M-2 Landfill site at concentrations that exceed the respective GWQC and are considered COC. Comparison with groundwater analytical data from relatively deeper monitoring wells, such as MW-19, suggests that VOC appear to be limited to the shallow portion of the saturated zone.

3.2.3 Landfill Near-Surface Soils Investigation

To characterize near surface soils (0 to 2 ft) at the M-2 Landfill, the DPW installed soil borings and obtained soil samples between November 1998 and June 1999 at 196 locations. The evaluation of near-surface soils of the M-2 Landfill is detailed in a separate RIR entitled, *Remedial Investigation Report for Near-Surface Soils M-2 Landfill, Draft Report, July 2000* (Versar, 2000). All soil samples were analyzed for VOC, SVOC, pesticides/PCB and metals. The data for samples that exceeded the laboratory MDL and/or the respective NJDEP RDCSCC were evaluated to determine compliance with the respective NJDEP RDCSCC (Versar, 2000). A summary of analytical results along with the conclusions and recommendations of this investigation are provided below.

Volatile Organic Compounds (VOC)

A total of 196 boring samples were collected at 24 inches bgs and analyzed for VOC. No VOC exceeded the respective NJDEP RDCSCC.

Semi-Volatile Organic Compounds (SVOC)

A total of 196 soil boring samples were collected at 6 to 12 inches bgs and analyzed for SVOC. At 12 boring locations, seven SVOC were detected at concentrations exceeding the NJDEP

RDCSCC for soils. Exceedence locations were generally scattered across the landfill. The sample locations with exceedences were grouped and evaluated for the seven SVOC utilizing "compliance averaging". The results showed that, except for benzo(a)pyrene, the calculated compliance averages for the SVOC detections were below the respective RDCSCC, the exceedence was considered marginal, or an isolated location and a "de minimus" quantity (i.e., a small amount of contaminated soil, surrounded by sample concentrations either below the RDCSCC and/or non-detect) was present, and no further action is warranted.

Benzo(a)pyrene was detected in 12 borings above the RDCSCC of 0.66 mg/Kg. The exceedence concentrations ranged from 0.73J mg/Kg to 10 mg/Kg. The maximum background concentration for benzo(a)pyrene is 0.6 mg/Kg. A more stringent compliance criterion was used for benzo(a)pyrene because, as described in the Spring 1995 Site Remediation News (Volume 7 Number 2), NJDEP guidance regarding the use of multiplication factors (initially applied to the RDCSCC to limit the maximum allowable concentration for individual samples) had changed. Current NJDEP guidance regarding benzo(a)pyrene prescribes the application of multiplication factors to health-based criteria, not to a RDCSCC. The health based criteria for benzo(a)pyrene in soil is 0.09 mg/Kg. Applying the 10x factor to 0.09 mg/Kg means that no individual sample may exceed 0.9 mg/Kg for the purposes of compliance averaging. Using this criterion, only four of the 12 exceedences could be used for compliance averaging. These four exceedences all fell below 0.9 mg/Kg and slightly above the RDCSCC (0.66 mg/Kg) and were considered marginal. The other exceedences were considered to be marginal or de minimis quantities because the surrounding borings contained concentrations of benzo(a)pyrene below the RDCSCC or below detection. No further action is recommended for benzo(a)pyrene.

Pesticides/PCB

Eleven of the 196 boring samples exceeded the respective NJDEP RDCSCC for pesticides/PCB. Only three pesticides (4,4'-DDT, Dieldrin, and 4,4'-DDE) and four PCB compounds (Arochlor 1242, 1254, 1258, and 1260) were detected at concentrations exceeding the respective RDCSCC. Sample locations with exceedences were randomly scattered across the landfill. For the purpose of further evaluating the results, the exceedences were grouped and compliance averaging was performed where applicable/appropriate. The results showed that the calculated compliance averages for the three pesticides and four PCB exceedences were either below the respective RDCSCC, the exceedence was considered marginal, or an isolated location and a de minimus quantity existed. No further action is recommended for pesticides/PCB.

Metals

Nineteen of the 196 boring samples contained one or more metal concentrations above the respective NJDEP RDCSCC. Within the 19 borings, seven metals exceeded their respective RDCSCC. These included arsenic, beryllium, cadmium, nickel, zinc, lead, and mercury. Sample locations with exceedences were generally scattered along the northern edge of the landfill with some also located along the southern edge.

The exceedences for five of the metals (lead, mercury, nickel, zinc, and cadmium) occurred in isolated borings across the landfill. The analytical results for these five metals were either below

the respective RDCSCC, the exceedence was considered marginal, or an isolated location and a de-minimus quantity existed. No further action is warranted.

Beryllium was detected above the RDCSCC of 2.0 mg/Kg in seven borings. The exceedence concentrations ranged from 2.03 mg/Kg to 10.6 mg/Kg. The maximum background concentration for beryllium is 2.0 mg/Kg. The seven exceedences were randomly scattered along the northwestern edge of the landfill and did not indicate a particular source area. NJDEP guidance states that, for beryllium, no sample may exceed 2 mg/Kg for the purpose of compliance averaging. But, given the low average exceedence, a maximum background concentration equal to the RDCSCC, the isolated and scattered distribution of the exceedences, and the low concentrations in the surrounding samples, no further action is warranted for beryllium.

Arsenic was detected above the RDCSCC of 20 mg/Kg in nine borings. The arsenic exceedences were scattered across the landfill and did not indicate a particular source. The exceedence concentrations ranged from 21.2 mg/Kg to 81.3 mg/Kg. The Fort Monmouth – Main Post maximum background concentration for arsenic in soils is 22.9 mg/Kg (WESTON, 1995). Compliance averaging was not performed for arsenic because, as described in the guidance published in the Spring 1995 Site Remediation News by NJDEP, the 20 mg/Kg RDCSCC for arsenic is already 50 times higher than the health based number for arsenic (0.4 mg/Kg). Therefore, individual samples cannot exceed the RDCSCC unless a site-specific remediation standard is developed. The Spring 1995 guidance also states that exceedences of the arsenic RDCSCC due to natural background conditions would not require cleanup, but would require a site-specific remediation standard to document that the local natural background was greater than the RDCSCC. Given the scattered distribution of the arsenic exceedences, the maximum background concentration for arsenic, and the low concentrations in the surrounding samples, no further action for arsenic is warranted.

Although exceedences of NJDEP RDCSCC are identified in the near surface soils for SVOC, pesticides/PCB, and metals within the landfill, evaluation of the analytical results did not define a “source area” or level of contamination that necessitated the identification and evaluation of potential remedial actions. Either the specific calculated compliance average was below the respective RDCSCC, the exceedence was considered marginal, or an isolated location and a de minimus quantity was detected. No further action is warranted for the near surface soils. However, to address the PCB detected in the near surface soils, the DPW will incorporate a document equivalent to a Declaration of Environmental Restriction (DER) into the Fort Monmouth Master Plan for soils containing PCB.

3.2.4 Groundwater Investigation

A total of 24 groundwater monitoring wells have been installed and incorporated into the monitoring program at the M-2 Landfill. The wells have been installed to characterize the shallow groundwater at two distinct depth intervals: approximately 13 – 22 ft bgs, a depth interval considered to be within the fill, and 30 - 50 ft bgs, a depth considered to be well below any fill material.

As discussed in Section 2, three (3) groundwater monitoring wells (MW-1, MW-2, and MW-3) were installed by WESTON in late 1994 as part of the SI to initially characterize the groundwater at the M-2 Landfill. At that time, MW-1 was determined to be upgradient and MW-2 and MW-3 downgradient. Further, results of tidal monitoring performed during the SI indicated that there was no apparent relationship between the changing creek water levels and observed water levels in the upgradient well MW-1; however, a direct relationship was observed between changing creek water levels and the observed water levels in downgradient wells MW-2 and MW-3. MW-4 was then installed in February 1998, followed by the installation of six additional monitoring wells (MW-5, -6, -7, -8, -9, and -10) during the third and fourth quarters of 1998. Well logs and well construction summaries are included in the SI Report (WESTON, 1995) and also in **Appendix B** of this report. Approximate locations of the monitoring wells are depicted in **Figure 9**.

In April 2000, Versar provided oversight for the installation of 14 monitoring wells, MW-11 through MW-24, which were subsequently sampled in May and June 2000. The approximate locations of these wells are depicted on **Figure 9**. One set of wells was installed in the fill to a depth of 20 feet bgs (Wells MW13, MW14, MW15, MW16, MW17, MW18, MW21, MW22, MW23 and MW24) with a 15-foot screen interval from 5 feet to 20 ft bgs in each well. A second set of wells was installed deeper in the native material beneath the fill to a depth of 50 ft bgs (Wells MW11, MW12, MW19, and MW20) with a 20-foot screen interval from 30 ft to 50 ft bgs (see well logs in **Appendix B**). An all-terrain, hollow-stem, auger drill rig was used to advance the boring at each well location. The wells were constructed of 4-inch diameter schedule 40 PVC screen (0.010 slot) and PVC casing. The annular space surrounding each well screen was filled with #1 Morie sand to a level at least two ft above the top of screen. A one-foot thick bentonite plug was placed above the sand pack of each well, and the remainder of the annular space surrounding each well was filled with cement/bentonite grout to ground surface. Each well was completed with a 3-foot PVC casing stick up (above ground surface), and protected by a 6-inch diameter steel protective casing. Upon completion, the wells were developed using a submersible pump until the groundwater was visibly free of sediment. The wells were installed and developed by CT&E Drilling Services, Inc., a licensed New Jersey drilling company. The wells were installed in accordance with standard NJDEP procedures for the installation of wells in unconsolidated materials. Monitoring well logs, construction details, and monitoring well records are included as **Appendix B**.

A summary of the groundwater monitoring wells installed at the M-2 Landfill, including the total well depth and screened interval, is provided below:

Summary of Groundwater Monitoring Wells at the M-2 Landfill

Monitoring Well No.	Date of Installation	Total Well Depth (feet)	Screened Interval (feet)
MW-1	14 December 1994	22	7 - 22
MW-2	13 December 1994	18	7.5 - 17
MW-3	13 December 1994	16	5 - 15
MW-4	17 December 1997	19	7 – 19*
MW-5	24 August 1998	13	3 – 13*
MW-6	24 August 1998	15	3 – 15*
MW-7	24 August 1998	15	5 – 15*
MW-8	24 August 1998	15	5 - 15*
MW-9	24 August 1998	15	5 - 15*
MW-10	31 August 1998	20	5 - 20*
MW-11	4 May 2000	50	30 - 50
MW-12	5 May 2000	50	30 - 50
MW-13	8 May 2000	20	5 - 20
MW-14	19 April 2000	20	5 – 20
MW-15	8 May 2000	20	5 – 20
MW-16	8 May 2000	20	5 – 20
MW-17	3 May 2000	20	5 - 20
MW-18	2 May 2000	20	5 - 20
MW-19	3 May 2999	50	30 - 50
MW-20	2 May 2000	50	30 - 50
MW-21	3 May 2000	20	5 - 20
MW-22	3 May 2000	20	5 - 20
MW-23	8 May 2000	20	5 - 20
MW-24	4 May 2000	20	5 – 20

* Approximate screen interval. Shaded cells represent the deeper wells.

The Fort Monmouth Quarterly Groundwater Monitoring Program was initiated in the 2nd Quarter (May) of 1997. The collected groundwater samples have been analyzed for TCL VOC (+15), TCL BNA (+15), TCL pesticides/PCB, and TAL metals. The results of the 12 rounds conducted through March 2000 as well as the initial two rounds of sampling performed for monitoring wells MW-5 through MW-10 in October/November 1998 and then MW-11 through MW-24 in May/June 2000 are presented in **Table 5** and are summarized below. Groundwater contour maps for each sampling quarter are presented in **Figures 8a** through **8o**. The groundwater elevation contours were generated from groundwater level measurements made during the quarterly sampling of the monitoring wells. The figures indicate that groundwater flow is consistently north-northwest, towards Mill Creek at a gentle gradient of 0.03 (approximately 3 ft of vertical drop for every 100 ft of horizontal distance). The locations of the groundwater monitoring wells are shown on **Figure 9**.

As presented in the SI Report (WESTON, 1995), several natural and anthropogenic factors contribute to the wide range in concentrations of metals in soils, which further impact the concentration of metals in groundwater. Soils derived from the glauconitic sands contain abundant aluminum, calcium, potassium, iron, magnesium, and manganese (among others), which are likely to be present at elevated concentrations in the groundwater, particularly when sediments are entrained in the collected groundwater samples. A low flow sampling methodology was proposed for use by the DPW and accepted by the NJDEP to assess the impact of entrained sediments on the dissolved phase metal concentrations at the site (discussed in **Appendix C**). Using a low flow sampling methodology to reduce the presence of entrained sediment yielded substantial reductions in the dissolved phase concentrations of metals, such as arsenic, antimony, beryllium, cadmium, chromium, cobalt, lead, mercury, selenium, silver, thallium, and vanadium. Significant decreases in the concentrations of metals characteristic of glauconitic sand also were observed. These included aluminum, barium, calcium, copper, iron, magnesium, manganese, nickel, potassium, sodium, and zinc.

The detected parameters for each monitoring well have been compared to the respective GWQC and for metals the respective GWQC and Fort Monmouth – Main Post Maximum Background Concentrations (MBC), presented below, to determine contaminants of concern requiring further evaluation.

Fort Monmouth Main Post – Summary of Site Specific and Monmouth County Groundwater Maximum Background Concentrations

Metals (Total)	Fort Monmouth – Main Post Maximum Background Concentrations (ug/L)	Monmouth County [1] (maximum) (ug/L)
Aluminum	121,000	NLE
Antimony	20.7	NLE
Arsenic	89.3	NLE
Barium	699	400
Beryllium	2.1	7
Calcium	45,400	7,300
Cadmium	9.5	6
Cobalt	18.3	NLE
Chromium	191	<50
Copper	65.6	730
Cyanide	ND	NLE
Iron	431,000	27,000
Lead	22.7	<100
Magnesium	62,700	25,000
Mercury	0.26	NLE
Manganese	331	480
Nickel	187	NLE
Potassium	137,000	10,000

Metals (Total)	Fort Monmouth – Main Post Maximum Background Concentrations (ug/L)	Monmouth County [1] (maximum) (ug/L)
Silver	ND	<10
Sodium	21,500	197,000
Selenium	29.6	NLE
Thallium	5.5	NLE
Vanadium	108	NLE
Zinc	233	60

Source: Table 4.1-6, WESTON, 1995
NLE – No level established.
[1] – From Table 9 in Harriman and Sargent, 1985.

The analytical results of the sampling events (including metals) are discussed below for each of the site wells.

Monitoring Well MW-01

Twelve (12) rounds of groundwater sampling have been conducted to-date at MW-01 (May 1997 – March 2000). There were two VOC detected, acetone and methyl-tert-butyl ether. Acetone was detected during one sampling event at 7.27 ug/L, which is below the GWQC of 700 ug/L. Methyl-tert-butyl ether was also detected during only one sampling event at 1.02 ug/L (there is no GWQC for methyl-tert-butyl ether).

There were seven SVOC detected during the 12 sampling rounds: 2-methylnaphthalene (1 detection); 4-methylphenol (1 detection); bis(2-ethylhexyl)phthalate (3 detections); butylbenzylphthalate (2 detections); diethlyphthalate (1 detection); di-n-butylphthalate (3 detections), and naphthalene (1 detection). The SVOC detections were either all below the respective GWQC or no GWQC existed for that parameter.

Two pesticides were detected during the 12 sampling rounds (4,4'-DDE and 4,4'-DDT). Each was detected only once, and at a concentration that did not exceed the respective GWQC. There were no PCB detected during the 12 sampling rounds.

A total of 21 metals were detected during the 12 sampling rounds. Of the 21 metals detected, 16 metals (arsenic, barium, beryllium, calcium, chromium, cobalt, copper, magnesium, mercury, nickel, potassium, silver, sodium, thallium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Five metals (aluminum, cadmium, iron, lead, and manganese) were detected above their respective GWQC, but none are identified as COC.

Of the naturally occurring metal constituents, aluminum, iron, and manganese were detected in MW-01. Aluminum was detected during 11 of the 12 sampling rounds at concentrations ranging from 236.3 ug/L to 2,480 ug/L. All of the detections exceeded the GWQC for aluminum of 200 ug/L, but did not exceed the MBC of 121,000 ug/L. Iron was detected in all 12 sampling rounds ranging from 100 ug/L to 7,790 ug/L, with ten of the detections exceeding the GWQC of 300

ug/L, but none of the detections exceeding the MBC of 431,000 ug/L. Manganese was detected in all 12 of the sampling rounds ranging from 73.1 ug/L to 4,940 ug/L, with all eleven detections exceeding the GWQC of 50 ug/L and one of the detections exceeding the MBC of 331 ug/L. Only a single exceedence for manganese (4,940 ug/L) was significantly greater than the MBC of 331 ug/L, and this result is considered to be anomalous. None of these constituents (aluminum, iron, manganese) are identified as COC.

Cadmium was detected in ten sampling rounds ranging from 1.53 ug/L to 6.23 ug/L, with one detection exceeding the GWQC of 4 ug/L. Lead was detected in three sampling rounds ranging from 4.10 ug/L to 11.0 ug/L, with the detection at 11.0 ug/L exceeding the GWQC of 10 ug/L. Based on the frequency of occurrence and the concentration ranges for these metals, as well as detections in adjacent monitoring well locations, lead and cadmium are not identified as COC.

Monitoring Well MW-02

Twelve (12) rounds of groundwater sampling have been conducted to-date at MW-02 (May 1997 – March 2000). There were eight VOC detected during the 12 sampling rounds. 1,2-DCB was detected during two sampling rounds at 1.22 ug/L and 1.35 ug/L, below the GWQC of 600 ug/L. 1,3-DCB was detected during three sampling rounds ranging from 1.26 ug/L to 1.98 ug/L, below the GWQC of 600 ug/L. 1,4-DCB was detected during seven sampling rounds ranging from 1.96 ug/L to 4.87 ug/L, below the GWQC of 75 ug/L. Acetone was detected during one sampling event at 8.77 ug/L, below the GWQC of 700 ug/L. Carbon disulfide was detected during one sampling event at 1.30 ug/L (there is no GWQC for carbon disulfide). Tert-Butyl alcohol was detected during one sampling event at 35.15 ug/L (there is no GWQC for tert-butyl alcohol). Benzene was detected during nine sampling events ranging from 1.36 ug/L to 6.44 ug/L, with all nine of the detections exceeding the GWQC of 1 ug/L. CB was detected during all 12 of the sampling events ranging from 7.39 ug/L to 69.55 ug/L, with all 12 of the detections exceeding the GWQC of 4 ug/L. Both benzene and CB are considered to be COC.

There were eight SVOC detected during the 12 sampling rounds: 1,3-DCB (1 detection); 1,4-DCB (8 detections); 2-methylnaphthlene (1 detection); 4-methylphenol (1 detection); bis(2-ethylhexyl)phthalate (4 detections); butylbenzylphthalate (1 detection); di-n-butylphthalate (4 detections); and n-nitrosodiphenylamine (1 detection). The SVOC detections were either all below the respective GWQC or no GWQC existed for that parameter. There were no pesticides or PCB detected during the 12 sampling rounds.

A total of 22 metals were detected during the 12 sampling rounds. Of the 22 metals detected, 19 metals (aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, lead, magnesium, mercury, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Three metals (iron, manganese, and silver) were detected above their respective GWQC, but none are identified as COC.

Iron was detected in all 12 sampling rounds ranging from 13,200 ug/L to 82,680 ug/L, with all of the detections exceeding the GWQC of 300 ug/L, but none of the detections exceeding the MBC of 431,000 ug/L. Manganese was detected in all 12 sampling rounds ranging from 145.4 ug/L to

474 ug/L, with all of the detections exceeding the GWQC of 50 ug/L and three of the detections exceeding the MBC of 331 ug/L. However, manganese is regarded as a naturally occurring metal within the native soil types at Fort Monmouth and is not considered to be a COC.

Silver was detected only during the first sampling round at 41.0 ug/L, which exceeds the GWQC of 20 ug/L. This detection is most likely attributable to a laboratory error since the laboratory calibration blank reported a result greater than the GWQC for silver. Silver has not been detected again, since the first sampling round.

Monitoring Well MW-03

Twelve (12) rounds of groundwater sampling have been conducted to-date at MW-03 (May 1997 – March 2000). There were three VOC detected, 1,4-DCB, benzene, and CB. 1,4-DCB was detected during four sampling events ranging from 1.30 ug/L to 9.32 ug/L, with none of the detections exceeding the GWQC of 75 ug/L. Benzene was detected during five sampling rounds ranging from 1.31 ug/L to 4.26 ug/L, with all of the detections exceeding the GWQC of 1.0 ug/L. CB was detected during all 12 sampling events ranging from 1.49 ug/L to 107.81 ug/L, with eight of the detections exceeding the GWQC of 4 ug/L. CB and benzene are both considered to be COC.

There were 11 SVOC detected during the 12 sampling rounds: 1,4-DCB (2 detections); 4-nitrophenol (1 detection); acenaphthene (3 detections); anthracene (1 detection); bis(2-ethylhexyl)phthalate (1 detection); butylbenzylphthalate (1 detection); didibenzofuran (2 detections); di-n-butylphthalate (4 detections); fluorene (2 detections); naphthalene (3 detections), and phenanthrene (2 detections). The SVOC detections were either all below the respective GWQC or no GWQC existed for that parameter. Additionally, there has been no detection of SVOC over the last four sampling rounds (i.e., since the 1st Quarter of 1999).

There was one detection for one pesticide (gamma-BHC at 0.020 ug/L) during the 12 sampling rounds and this detection was below the respective GWQC. There were no detections for PCB during the 12 sampling rounds.

A total of 22 metals were detected during the 12 sampling rounds. Of the 22 metals detected, 18 metals (aluminum, antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, magnesium, mercury, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC exists for the detected metal. Four metals (iron, lead, manganese, and silver) were detected above their respective GWQC, but none are identified as COC.

Two of the four metals are considered to be naturally occurring within the native soil types at Fort Monmouth. Iron was detected in all 12 sampling rounds ranging from 9,300 ug/L to 69,260 ug/L, with all of the detections exceeding the GWQC of 300 ug/L, but none of the detections exceeding the MBC of 431,000 ug/L. Manganese was detected in all 12 sampling rounds ranging from 395 ug/L to 5,890 ug/L, with all of the detections exceeding the GWQC of 50 ug/L and the MBC of 331 ug/L. The trend represented by the manganese results in MW-03 does not suggest that a contaminant source is present. Furthermore, based on the frequency of

occurrences and the magnitude of the detections at adjacent monitoring well locations, manganese it is not identified as a COC.

Lead was detected in seven sampling rounds ranging from 1.1 ug/L to 13.0 ug/L, with only the detection at 13.0 ug/L exceeding the GWQC of 10 ug/L. Silver was detected only during the first two sampling rounds at 36.0 ug/L and 9,170 ug/L, respectively, which exceeded the GWQC of 20 ug/L. The detection for silver during the first sampling round (36.0 ug/L) is most likely attributable to a laboratory error since the respective laboratory calibration blank reported a result greater than the GWQC for silver. It is also likely that the detection reported during the second sampling round (9,170 ug/L) is attributable to laboratory error since this result is an order of magnitude greater than any other reported result for silver at the M-2 Landfill, and silver has not been detected again at MW-03 since the first two sampling rounds.

Monitoring Well MW-04

During the nine rounds of groundwater sampling conducted to-date at MW-04 (February 1998 – March 2000), there were two VOC detected, benzene and CB. Benzene was detected during one sampling event (October 1999) at 1.23 ug/L, which exceeds the GWQC of 1.0 ug/L. CB was detected during five sampling events, but only one detection (October 1999) at 5.96 ug/L exceeded the GWQC of 4 ug/L. Benzene and CB are considered to be COC.

There were six SVOC detected during the nine sampling rounds: benzo[g,h,l]perylene, butylbenzyphthalate, dibenz[a,h]anthracene, di-n-butylphthalate, indeno[1,2,3-cd]pyrene, and naphthalene. In each case, the six SVOC were only detected once and none of the detections exceeded the respective GWQC. There were no pesticides or PCB detected during the nine sampling rounds.

A total of 19 metals were detected during the nine sampling rounds. Of the 19 metals detected, 16 metals (arsenic, barium, cadmium, calcium, chromium, cobalt, copper, lead, magnesium, mercury, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC exists for the detected metal. Three naturally occurring metals (aluminum, iron, and manganese) were detected above their respective GWQC, but none are identified as COC.

Aluminum was detected during eight sampling rounds ranging from 20.0 ug/L to 514 ug/L. None of the detections exceeded the MBC for aluminum of 121,000 ug/L, but three of the detections (209 ug/L, 302 ug/L, and 514 ug/L), from sampling rounds conducted in 1998, exceeded the GWQC for aluminum of 200 ug/L. Iron was detected during all nine sampling rounds ranging from 17,800 ug/L to 43,000 ug/L. None of the detections exceeded the MBC for iron of 431,000 ug/L, but all nine of the detections exceeded the GWQC for iron of 300 ug/L. Manganese was detected during all nine sampling rounds ranging from 180 ug/L to 2,010 ug/L. Six of the detections exceeded the MBC for manganese of 331 ug/L and all nine of the detections exceeded the GWQC of 50 ug/L. The trend represented by the manganese results in MW-04 does not suggest that a contaminant source is present. Furthermore, based on the frequency of occurrences and the magnitude of the detections at the location and in adjacent monitoring wells, manganese is not identified as a COC.

Monitoring Well MW-05

During the seven rounds of groundwater sampling conducted to-date at MW-05 (October 1998 – March 2000), there were two VOC detected, acetone and 2-butanone. Acetone was detected during one sampling event at 5.49 ug/L and 2-butanone was detected during two sampling events at 3.19 ug/L and 9.29 ug/L. None of the detections for acetone and 2-butanone exceeded the respective GWQC.

There were two SVOC detected during the seven sampling rounds: bis(2-ethylhexyl)phthalate and di-n-octylphthalate. Bis(2-Ethylhexyl)phthalate was detected during one sampling event at 40.9 ug/L, which slightly exceeded the GWQC of 30 ug/L. Di-n-octylphthalate was detected during one sampling event at 1.58 ug/L, which was below the GWQC of 100 ug/L. No SVOC constituents are considered to be COC.

There were no pesticides or PCB detected during the seven sampling rounds.

A total of 20 metals were detected during the seven sampling rounds. Of the 20 metals detected, 16 metals (antimony, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, magnesium, manganese, mercury, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Four metals (aluminum, arsenic, iron, and lead) were detected above their respective GWQC, but none are identified as COC.

Aluminum was detected during all seven sampling rounds ranging from 370 ug/L to 4,860 ug/L. All of the detections exceeded the GWQC for aluminum of 200 ug/L, but did not exceed the MBC for aluminum of 121,000 ug/L. Iron was detected during all seven sampling rounds ranging from 15,800 ug/L to 74,400 ug/L. None of the detections exceeded the MBC for iron of 431,000 ug/L, but all seven of the detections exceeded the GWQC for iron of 300 ug/L. These naturally occurring metals are typically present in native soils at Fort Monmouth and are not identified as COC.

Arsenic was detected in five sampling rounds ranging from 2.80 ug/L to 8.63 ug/L. Only one detection (8.63 ug/L) reported during the November 1998 sampling event exceeded the GWQC for arsenic of 8 ug/L. Since the November 1998 sampling round, the four subsequent reported detections for arsenic have all been below the GWQC. Lead was detected in all seven sampling rounds ranging from 4.09 ug/L to 15.5 ug/L. Only one detection (15.3 ug/L) reported during the November 1998 sampling event exceeded the GWQC for lead of 10 ug/L. Since the November 1998 sampling round, the five subsequent reported detections for lead have all been below the GWQC.

Monitoring Well MW-06

During the seven rounds of groundwater sampling conducted to-date at MW-06 (October 1998 – March 2000), three VOC were detected: 2-butanone, acetone, and CB. 2-Butanone was detected during two sampling events at 4.65 ug/L and 8.86 ug/L. Acetone was detected during one

sampling event at 7.45 ug/L and CB was detected during one sampling event at 1.36 ug/L. None of the detections for 2-butanone, acetone, or CB exceeded the respective GWQC.

There were no SVOC detected during the seven sampling rounds. There were three PCB detected during the seven sampling rounds. Arochlor 1016 was detected during three sampling rounds at 0.611 ug/L, 0.865 ug/L, and 2.260 ug/L, above the GWQC for PCB of 0.50 ug/L. Arochlor 1260 was detected once at 0.581 ug/L, above the GWQC for PCB of 0.50 ug/L. Gamma-BHC was detected during one sampling round at 0.058 ug/L, which was below the GWQC of 0.20 ug/L.

A total of 22 metals were detected during the seven sampling rounds. Of the 22 metals detected, 15 metals (barium, beryllium, cadmium, calcium, cobalt, copper, magnesium, mercury, nickel, potassium, silver, sodium, thallium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Seven metals (aluminum, antimony, arsenic, chromium, iron, lead, and manganese) were detected above their respective GWQC, but none are identified as COC.

Aluminum was detected during all seven sampling rounds ranging from 616 ug/L to 10,300 ug/L. All of the detections exceeded the GWQC for aluminum of 200 ug/L, but did not exceed the MBC for aluminum of 121,000 ug/L. Iron was detected during all seven sampling rounds ranging from 16,500 ug/L to 50,700 ug/L. None of the detections exceeded the MBC for iron of 431,000 ug/L, but all seven of the detections exceeded the GWQC for iron of 300 ug/L. Manganese was detected during all seven sampling rounds ranging from 52.4 ug/L to 247 ug/L. None of the detections exceeded the MBC for manganese of 331 ug/L, but all seven of the detections exceeded the GWQC of 50 ug/L. These metals are considered to be naturally occurring within the native soil types present at Fort Monmouth and are not identified as COC.

Antimony was detected in two sampling rounds at 3.76 ug/L and 566 ug/L. The detection at 566 ug/L during the March 2000 sampling event exceeded the GWQC for antimony of 20 ug/L. MW-06 has been sampled during three subsequent sampling events in June, September, and December 2000, and the reported results for antimony have all been non-detect (ND). (These analytical results will be submitted to the NJDEP under separate cover at a later date.)

Arsenic was detected in two sampling rounds at 16.5 ug/L (November 1998) and at 5.60 ug/L (March 2000). The November 1998 results exceeded the GWQC for arsenic of 8 ug/L. Since the November 1998 detection, the only other detection for arsenic did not exceed the GWQC. Chromium was detected in all seven sampling rounds ranging from 6.40 ug/L to 16,000 ug/L. Two of the detections for chromium exceeded the GWQC of 100 ug/L, and the highest detected concentration of 16,000 ug/L reported during the March 2000 sampling event was anomalous. The reported results for chromium from the three subsequent sampling events at MW-06 in June, September, and December 2000, have been 10.3 ug/L, 1.59 ug/L and ND, respectively. All were below the GWQC.

Lead was detected in six sampling rounds ranging from 6.26 ug/L to 90.5 ug/L. The detections from the first three sampling rounds, 13.6 ug/L, 22.4 ug/L, and 90.5 ug/L, respectively, exceeded

the GWQC of 10 ug/L. However, the reported results for lead over the four subsequent sampling rounds have all been below the GWQC.

Antimony, arsenic, chromium, and lead are not identified as COC based upon the most recent laboratory data.

Monitoring Well MW-07

During the seven rounds of groundwater sampling conducted to-date at MW-07 (October 1998 – March 2000), there were two VOC detected, acetone and 2-butanone. Acetone was detected during one sampling event at 6.63 ug/L and 2-butanone was detected during three sampling events at 5.45 ug/L, 11.10 ug/L, and 11.29 ug/L. None of the detections for acetone and 2-butanone exceeded the respective GWQC.

There were no SVOC, pesticides, or PCB detected during the seven sampling rounds.

A total of 21 metals were detected during the seven sampling rounds. Of the 21 metals detected, 17 metals (antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, magnesium, mercury, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Four metals (aluminum, iron, lead, and manganese) were detected above their respective GWQC, but none are identified as COC.

Aluminum was detected during all seven sampling rounds ranging from 248 ug/L to 3,870 ug/L. All of the detections exceeded the GWQC for aluminum of 200 ug/L, but none exceeded the MBC for aluminum of 121,000 ug/L. Iron was detected during all seven sampling rounds ranging from 14,800 ug/L to 118,000 ug/L. None of the detections exceeded the MBC for iron of 431,000 ug/L, but all seven of the detections exceeded the GWQC for iron of 300 ug/L. Manganese was detected during all seven sampling rounds ranging from 70.1 ug/L to 156 ug/L. None of the detections exceeded the MBC for manganese of 331 ug/L, but all seven of the detections exceeded the GWQC for manganese of 50 ug/L.

Lead was detected in five of the sampling rounds ranging from 3.41 ug/L to 16.4 ug/L. The detections from the first two sampling rounds, 13.0 ug/L in October 1998 and 16.4 ug/L in November 1998 exceeded the GWQC for lead of 10 ug/L. Since the first two sampling rounds, the reported results for lead over the five subsequent sampling rounds have either been ND (2 rounds) or the detections were below the GWQC (3 rounds).

Monitoring Well MW-08

During the seven rounds of groundwater sampling conducted to-date at MW-08 (October 1998 – March 2000), three VOC were detected: 2-butanone, acetone and benzene. 2-Butanone was detected during two sampling events at 28.18 ug/L and 86.82 ug/L. Acetone was detected during two sampling events at 11.27 ug/L and 17.89 ug/L. None of the detections for acetone and 2-butanone exceeded the respective GWQC of 300 ug/L and 700 ug/L. Benzene was detected during five sampling events ranging from 2.66 ug/L to 7.46 ug/L. All five detections exceeded the GWQC for benzene of 1 ug/L. Benzene is considered to be a COC.

There were no SVOC, pesticides, or PCB detected during the seven sampling rounds.

A total of 20 metals were detected during the seven sampling rounds. Of the 20 metals detected, 15 metals (antimony, arsenic, barium, beryllium, calcium, chromium, cobalt, copper, magnesium, mercury, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Five metals (aluminum, cadmium, iron, lead, and manganese) were detected above their respective GWQC, but none are identified as COC.

Aluminum was detected during all seven sampling rounds ranging from 616 ug/L to 8,250 ug/L. All of the detections exceeded the GWQC for aluminum of 200 ug/L, but did not exceed the MBC for aluminum of 121,000 ug/L. Iron was detected during all seven sampling rounds ranging from 18,400 ug/L to 142,000 ug/L. None of the detections exceeded the MBC for iron of 431,000 ug/L, but all seven of the detections exceeded the GWQC for iron of 300 ug/L. Manganese was detected during all seven sampling rounds ranging from 55.1 ug/L to 74.6 ug/L. None of the detections exceeded the MBC for manganese of 331 ug/L, but all seven of the detections exceeded the GWQC of 50 ug/L. Aluminum, iron, and manganese are not identified as COC.

Cadmium was detected in four sampling rounds ranging from 0.925 ug/L to 4.14 ug/L, with the maximum detection slightly exceeding the GWQC of 4 ug/L. Lead was detected in all seven sampling rounds ranging from 3.37 ug/L to 45.0 ug/L. Four of the detections for lead exceeded the GWQC of 10 ug/L, but only the detection from the November 1998 sampling round (45.0 ug/L) was significantly greater than the remaining data for this well. The lead results reported from the last two sampling rounds (October 1999 and March 2000) have both been below the GWQC. Cadmium and lead are not identified as COC.

Monitoring Well MW-09

During the seven rounds of groundwater sampling conducted to-date at MW-09 (October 1998 – March 2000), there were four VOC detected, 2-butanone, acetone, benzene, and CB. 2-Butanone was detected during two sampling events at 3.19 ug/L and 5.47 ug/L. Acetone was detected during two sampling event at 6.22 ug/L and 6.30 ug/L. CB was detected during one sampling event at 1.99 ug/L. None of the detections for 2-butanone, acetone, or CB exceeded the respective GWQC of 300 ug/L, 700 ug/L and 4 ug/L. Benzene was detected during all seven sampling rounds ranging from 2.21 ug/L to 538.24 ug/L. All five of the detections for benzene exceeded the GWQC of 1 ug/L. In addition, the detections for benzene have steadily decreased from the maximum detection at 538.24 ug/L (October 1998) to 2.21 ug/L (March 2000). Benzene is identified as a COC.

There was one SVOC detected during the seven sampling rounds. Phenol was detected during one sampling round at 4.47 ug/L, below the GWQC for phenol of 4000 ug/L.

There were two pesticides detected during the seven sampling rounds. 4,4'-DDD was detected during two sampling rounds at 0.007 ug/L and 0.046 ug/L, which were below the GWQC of 0.10

ug/L. 4,4'-DDE was detected during one sampling round at 0.033 ug/L which was below the GWQC of 0.10 ug/L. There were two PCB detected during the seven sampling rounds. Arochlor 1016 was detected during three sampling rounds at 0.244 ug/L, 0.260 ug/L, and 0.700 ug/L, with the highest detection exceeding the GWQC for PCB of 0.50 ug/L. Arochlor 1254 was detected during four sampling events ranging from 1.187 ug/L to at 3.850 ug/L. All four of the detections exceeded the GWQC for PCB of 0.50 ug/L. Due to the relative insolubility and immobility of PCB in the groundwater and the low occurrence at the site, the PCB are not identified as COC. Furthermore, a low flow sampling approach was employed by the DPW to further discount the detection of PCB (and metals) at the site, which is discussed in the subsequent paragraphs.

A total of 22 metals were detected during the seven sampling rounds. Of the 22 metals detected, 15 metals (antimony, barium, beryllium, calcium, cobalt, copper, magnesium, mercury, nickel, potassium, selenium, silver, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Seven metals (aluminum, arsenic, cadmium, chromium, iron, lead, and manganese) were detected above their respective GWQC, but none are identified as COC.

Aluminum was detected during all seven sampling rounds ranging from 616 ug/L to 8,250 ug/L. All of the detections exceeded the GWQC for aluminum of 200 ug/L, but did not exceed the MBC of 121,000 ug/L. Iron was detected in all seven sampling rounds ranging from 10,400 ug/L to 99,300 ug/L, with all of the detections exceeding the GWQC of 300 ug/L, but none of the detections exceeding the MBC of 431,000 ug/L. Manganese was detected in all seven sampling rounds ranging from 1,200 ug/L to 4,260 ug/L, with all of the detections exceeding the GWQC of 50 ug/L and the MBC of 331 ug/L. Because the aluminum, manganese, and iron are considered to be natural constituents of the native soils at Fort Monmouth, and based on the trends at this location and adjacent monitoring wells, these constituents are not identified as a COC.

Arsenic was detected in five sampling rounds ranging from 3.90 ug/L to 22.1 ug/L, with two of the detections exceeding the GWQC of 8 ug/L. Cadmium was detected in six sampling rounds ranging from 0.987 ug/L to 15.2 ug/L, with three of the detections exceeding the GWQC of 4 ug/L. Chromium was detected in all seven sampling rounds ranging from 7.97 ug/L to 309 ug/L, with two of the detections exceeding the GWQC of 100 ug/L. Lead was detected in all seven sampling rounds ranging from 7.00 ug/L to 95.9 ug/L, with six of the detections exceeding the GWQC of 10 ug/L. Based on the relatively minor nature of the exceedances at this location, the frequency of detections at the site, and the data trends for this well and adjacent wells, the arsenic, cadmium, chromium and lead are not identified as COC.

During evaluation of the Quarterly Groundwater Monitoring Program results, the DPW attempted to determine if the detected PCB and specific metal concentrations observed primarily in the groundwater samples from MW-06 and MW-09 were a function of contaminated sediments entrained in the monitoring well during the course of well purging and sampling activities, or an accurate representation of aquifer/groundwater conditions. The DPW proposed to the NJDEP to sample these wells using a low flow sampling technique. Monitoring wells

MW-6 and MW-9 were sampled twice (January 5 and January 27, 2000) using low flow techniques. The results of the low flow sampling for lead and PCB were ND, showing that the reported lead and PCB concentrations were most likely attributable to sediment entrained in the samples during the sampling event and not representative of actual groundwater conditions.

As shown below, similar results were observed for many of the remaining metals, particularly the metals regarded as uncharacteristic of the site soils (arsenic, antimony, beryllium, cadmium, chromium, cobalt, lead, mercury, selenium, silver, thallium, vanadium). Significant decreases in the concentrations of metals were also observed for many of the more commonly occurring soil constituents, such as: aluminum, barium, calcium, copper, iron, magnesium, manganese, nickel, potassium, sodium, and zinc. However, these more common constituents were consistently observed even when the low-flow sampling methodology was performed.

Fort Monmouth Main Post – Comparison of Quarterly Groundwater Sampling and Low Flow Sampling at MW-09

Metals (Total)	Range of Quarterly Groundwater Sampling Results MW-09 (ug/L)	Result of Low Flow Sampling Performed 6 January 2000 (ug/L)	NJDEP Groundwater Quality Criteria (ug/L)
Aluminum	**455 – 32,300**	**385**	200
Antimony	ND – 4.08	ND	20
Arsenic	ND – **22.1**	ND	8
Barium	77.5 – 279	56.9	2,000
Beryllium	ND – 4.47	ND	20
Cadmium	ND – **15.2**	ND	4
Calcium	46,000 – 99,300	47,800	NLE
Chromium	7.97 - **309**	5.80	100
Cobalt	ND – 16.8	ND	NLE
Copper	ND - 193	99.0	1,000
Iron	**10,400 – 99,300**	**6,780**	300
Lead	7.0 – **95.9**	ND	10
Magnesium	5,260 - 14,100	4,250	NLE
Manganese	**1,200 – 4,260**	**1,070**	50
Mercury	ND – **3.46**	ND	2
Nickel	1.10 – 46.8	2.50	100
Potassium	6,860 – 31,600	5,680	NLE
Selenium	ND – 6.57	ND	50
Silver	ND – 4.9	ND	20
Sodium	4,560 – 10,500	7,360	50,000
Thallium*	ND	ND	10
Vanadium	3.29 - 145	2.0	NLE
Zinc	105 – 2,300	27.0	5,000

ND – Not Detected.
NLE – No Limit Established.
* Thallium has not been detected in any sampling rounds to-date at MW-09.

Monitoring Well MW-10

During the seven rounds of groundwater sampling conducted to-date at MW-07 (October 1998 – March 2000), there were two VOC detected: 2-butanone and acetone. 2-butanone was detected during three sampling events at 2.85 ug/L, 9.93 ug/L, and 12.64 ug/L. Acetone was detected during two sampling events at 5.21 ug/L and 9.04 ug/L. None of the detections for 2-butanone and acetone exceeded the respective GWQC of 300 ug/L and 700 ug/L.

There were no SVOC, pesticides, or PCB detected during the seven sampling rounds.

A total of 20 metals were detected during the seven sampling rounds. Of the 20 metals detected, 17 metals (antimony, arsenic, barium, beryllium, cadmium, calcium, chromium, cobalt, copper, lead, magnesium, mercury, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Three metals (aluminum, iron, and manganese) were detected above their respective GWQC, but none are identified as COC.

Aluminum was detected during all seven sampling rounds ranging from 98.4 ug/L to 5,610 ug/L. Six of the seven detections exceeded the GWQC for aluminum of 200 ug/L. None of the detections for aluminum exceeded the MBC of 121,000 ug/L. Iron was detected during all seven sampling rounds ranging from 4,280 ug/L to 65,600 ug/L. None of the detections exceeded the MBC for iron of 431,000 ug/L, but all seven of the detections exceeded the GWQC for iron of 300 ug/L. Manganese was detected during all seven sampling rounds ranging from 22.5 ug/L to 104 ug/L. None of the detections exceeded the MBC for manganese of 331 ug/L, but all four of the detections exceeded the GWQC for manganese of 50 ug/L. Aluminum, iron, and manganese are not identified as COC.

Monitoring Well MW-11

During the first two rounds of groundwater sampling conducted at MW-11 (May and June 2000), benzene was the only VOC detected. It was detected only during the May sampling event at 98.01 ug/L, which exceeded the GWQC of 1.0 ug/L. MW-11 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for benzene were 78.23 ug/L and 82.83 ug/L, respectively. (These analytical results will be submitted to the NJDEP under separate cover at a later date.)

MW-11 was screened from 30 –50 ft bgs and was installed at a depth below the fill material. Based on groundwater elevation data collected from Well MW-11 and from its shallower, downgradient sister well (Well MW-09) as shown in the Table below, an upward hydraulic gradient, ranging from 0.038 to 0.118, was observed in the MW-11 area.

Vertical Hydraulic Gradients in the MW-11 Area

Well No.	Screen Interval (ft bgs)	Top of Casing elevation (ft above MSL)	Date	Depth to Water (ft bgs)	Groundwater Elevation (ft above MSL	Vertical Hydraulic Gradient (ft/ft)

MW-9	5-15	14.09	9/28/00 12/29/00	10.11 10.80	3.98 3.29	0.038 "up" 0.118 "up"
MW-11	30 - 50	13.83	9/28/00 12/29/00	8.71 7.00	5.12 6.83	0.038 "up" 0.118 "up"

MSL – Mean Sea Level

This upward gradient, typical of an area bordering a stream, should prevent benzene detected in MW-11 from migrating deeper into the aquifer. In fact, it will facilitate the flushing of contaminants from MW-11 upward into the shallow portions of the aquifer where the proposed remedial action will effectively eliminate the benzene.

There were no SVOC, pesticides, or PCB detected during the two sampling events.

A total of 16 metals were detected during the two sampling rounds. Of the 16 metals detected, 14 metals (aluminum, antimony, barium, calcium, chromium, copper, magnesium, manganese, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Two metals (iron and lead) were detected above their respective GWQC, but neither is identified as a COC.

Iron was detected in both sampling events (397 ug/L and 306 ug/L) above the GWQC of 300 ug/L but below the MBC of 431,000 ug/L. Iron is a naturally occurring constituent of the soil types at Fort Monmouth and is not identified as a COC.

Lead was detected in the June sampling event at 84.5 ug/L, which was above the GWQC of 10 ug/L. However, MW-11 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were ND. (These analytical results will be submitted to the NJDEP under separate cover at a later date.)

Monitoring Well MW-12

During the two rounds of groundwater sampling conducted to-date at MW-12 (May and June 2000), there were no VOC detected. Bis(2-Ethylhexyl)phthalate was the only SVOC detected. Bis(2-Ethylhexyl)phthalate was detected during both sampling events at 1.81 ug/L and 3.04 ug/L, respectively, below the GWQC of 30 ug/L. There were no pesticides or PCB detected during the two sampling events.

A total of 15 metals were detected during the two sampling rounds. Of the 15 metals detected, 14 metals (aluminum, antimony, barium, calcium, chromium, copper, lead, magnesium, manganese, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. One metal (iron) was detected above its respective GWQC, but is not identified as a COC.

Iron was detected at 792 ug/L and 1,410 ug/L, which exceeded the GWQC for iron of 300 ug/L. However, these concentrations are both below the MBC for iron of 431,000 ug/L. Iron is not identified as a COC.

Monitoring Well MW-13

During the two rounds of groundwater sampling conducted to-date at MW-13 (May and June 2000), there were no VOC detected. Bis(2-Ethylhexyl)phthalate was the only SVOC detected. Bis(2-Ethylhexyl)phthalate was detected during one sampling event at 4.86 ug/L which was below the GWQC of 30 ug/L. There were no pesticides or PCB detected during the two sampling events.

A total of 15 metals were detected during the two sampling rounds. Of the 15 metals detected, 13 metals (aluminum, barium, calcium, chromium, cobalt, copper, lead, magnesium, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Two metals (iron and manganese) were detected above their respective GWQC during both sampling rounds, but neither is identified as a COC.

Iron was detected at 13,200 ug/L and 11,400 ug/L, which exceeded the GWQC for iron of 300 ug/L. Manganese was detected at 101 ug/L and 90.4 ug/L, which exceeded the GWQC for manganese of 50 ug/L. However, these detections were all below the respective MBC, which for iron is 431,000 ug/L and for manganese is 331 ug/L.

Monitoring Well MW-14

During the two rounds of groundwater sampling conducted to-date at MW-14 (May and June 2000), there were no VOC detected. Three SVOC were detected: 2-methylnaphthalene, acenaphthene, and naphthalene. 2-Methylnaphthalene was detected during one sampling event at 1.36 ug/L (there is no GWQC for 2-methylnaphthalene). Acenaphthene was detected during one sampling event at 1.19 ug/L, which is below the GWQC 400 ug/L. Naphthalene was detected during both sampling events at 1.59 ug/L and 3.46 ug/L, respectively (there is no GWQC for naphthalene). There were no pesticides or PCB detected during the two sampling events.

A total of 13 metals were detected during the two sampling rounds. Of the 13 metals detected, 10 metals (barium, calcium, chromium, magnesium, mercury, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Three metals (aluminum, iron and manganese) were detected above their respective GWQC during both sampling rounds, but are not identified as COC.

Aluminum was detected in one sampling event at 206 ug/L, which exceeded the GWQC of 200 ug/L. Iron was detected in both sampling events at 36,000 ug/L and 138,900 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L. Manganese was detected in both sampling events at 284 ug/L and 329 ug/L, which exceeded the GWQC for manganese of 50 ug/L. However, these detections are all below the respective MBC, which for aluminum is 121,000 ug/L, for iron is 431,000 ug/L, and for manganese is 331 ug/L.

Monitoring Well MW-15

During the two rounds of groundwater sampling conducted to-date at MW-15 (May and June 2000), toluene was the only VOC detected. Toluene was detected during both sampling rounds at 1.47 ug/L and 2.14 ug/L, respectively, which did not exceed the respective GWQC of 1000 ug/L. Eleven SVOC were detected during both sampling rounds: 2-methylnaphthalene, 4-methylphenol, acenaphthene, anthracene, benzoic acid, dibenzofuran, fluoranthene, fluorene, naphthalene, phenanthrene, and phenol. The detected values for the SVOC were all either below the respective GWQC or no GWQC existed. There were no pesticides or PCB detected during the two sampling events.

A total of 17 metals were detected during the two sampling rounds. Of the 17 metals detected, 13 metals (arsenic, barium, cadmium, calcium, chromium, cobalt, copper, magnesium, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Four metals (aluminum, iron, lead, and manganese) were detected above their respective GWQC. No metal constituents are identified as COC.

Aluminum was detected in both sampling events at 184 ug/L and 217 ug/L, respectively, with the June result exceeding the GWQC of 200 ug/L. However, neither reported result exceeded the MBC for aluminum of 121,000 ug/L. Iron was detected in both sampling events at 4,390 ug/L and 4,950 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L, but did not exceed the MBC of 431,000 ug/L. Manganese was detected in both sampling events at 85.2 ug/L and 79.1 ug/L, which exceeded the GWQC for manganese of 50 ug/L, but not the MBC of 331 ug/L. These constituents are considered to be naturally occurring in the soil types at Fort Monmouth and are not identified as COC.

Lead was detected in both sampling events at 14.0 ug/L and 41.5 ug/L, respectively, which exceeded the GWQC for lead of 10 ug/L. However, MW-15 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were ND and 6.57 ug/L, respectively, which were both below the GWQC. (These analytical results will be submitted to the NJDEP under separate cover at a later date.)

Monitoring Well MW-16

During the two rounds of groundwater sampling conducted to-date at MW-16 (May and June 2000), there were no VOC detected. Bis(2-Ethylhexyl)phthalate was the only SVOC detected. Bis(2-Ethylhexyl)phthalate was detected during one sampling event at 1.74 ug/L which was below the GWQC of 30 ug/L. There were no pesticides or PCB detected during the two sampling events.

A total of 14 metals were detected during the two sampling rounds. Of the 14 metals detected, 12 metals (aluminum, barium, cadmium, calcium, chromium, cobalt, copper, magnesium, nickel, potassium, sodium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Two metals (iron and manganese) were detected above their respective GWQC during both sampling rounds, but neither is identified as a COC.

Iron was detected in both sampling events at 7,660 ug/L and 13,700 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L. Manganese was detected in both sampling events at 280 ug/L and 247 ug/L, which exceeded the GWQC for manganese of 50 ug/L. However, these detections are all below the respective MBC, which for iron is 431,000 ug/L and for manganese is 331 ug/L.

Monitoring Well MW-17

During the two rounds of groundwater sampling conducted to-date at MW-17 (May and June 2000), there were no VOC, SVOC, pesticides, or PCB detected.

A total of 14 metals were detected during the two sampling rounds. Of the 14 metals detected, 12 metals (barium, calcium, chromium, cobalt, copper, magnesium, manganese, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Two metals (aluminum and iron) were detected above their respective GWQC during both sampling rounds, but neither is identified as a COC.

Aluminum was detected in both sampling events at 613 ug/L and 515 ug/L, respectively, which exceeded the GWQC for aluminum of 200 ug/L. Iron was detected in both sampling events at 767 ug/L and 325 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L. However, these detections are all below the respective MBC, which for aluminum is 121,000 ug/L and for iron is 431,000 ug/L. Aluminum and iron are not identified as COC.

Monitoring Well MW-18

During the two rounds of groundwater sampling conducted to-date at MW-18 (May and June 2000), there were no VOC, SVOC, pesticides, or PCB detected.

A total of 12 metals were detected during the two sampling rounds. Of the 12 metals detected, ten metals (aluminum, barium, calcium, chromium, magnesium, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Two metals (iron and manganese) were detected above their respective GWQC during both sampling rounds, but neither is identified as a COC.

Iron was detected in both sampling events at 13,300 ug/L and 11,000 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L. Manganese was detected in both sampling events at 140 ug/L and 137 ug/L, respectively, which exceeded the GWQC for manganese of 50 ug/L. However, these detections are all below the respective MBC, which for iron is 431,000 ug/L and for manganese is 331 ug/L. Iron and manganese are not identified as COC.

Monitoring Well MW-19

During the two rounds of groundwater sampling conducted to-date at MW-19 (May and June 2000), there were no VOC, SVOC, pesticides, or PCB detected.

A total of 16 metals were detected during the two sampling rounds. Of the 16 metals detected, 13 metals (antimony, barium, calcium, chromium, copper, magnesium, mercury, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their

respective GWQC or no GWQC existed for the detected metal. Three metals (aluminum, iron, and manganese) were detected above their respective GWQC, but none is identified as a COC.

Aluminum was detected in one sampling event at 555 ug/L, which exceeded the GWQC of 200 ug/L. Iron was detected in both sampling events at 1,860 ug/L and 830 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L. Manganese was detected in both sampling events at 74.4 ug/L and 66.7 ug/L, exceeding the GWQC for manganese of 50 ug/L. However, these detections are all below the respective MBC, which for aluminum is 121,000 ug/L, for iron is 431,000 ug/L, and for manganese is 331 ug/L. Aluminum, iron and manganese are not identified as COC.

Monitoring Well MW-20

During the two rounds of groundwater sampling conducted to-date at MW-20 (May and June 2000), there were no VOC, SVOC, pesticides, or PCB detected.

A total of 14 metals were detected during the two sampling rounds. Of the 14 metals detected, 12 metals (antimony, barium, calcium, chromium, copper, magnesium, manganese, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Two metals (aluminum and iron) were detected above their respective GWQC, but neither is identified as a COC.

Aluminum was detected in both sampling events and during May at 444 ug/L, which exceeded the GWQC for aluminum of 200 ug/L. Iron was detected in both sampling events at 2,040 ug/L and 437 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L. However, these detections are all below the respective MBC, which for aluminum is 121,000 ug/L and for iron is 431,000 ug/L. Aluminum and iron are not identified as COC.

Monitoring Well MW-21

During the two rounds of groundwater sampling conducted to-date at MW-21 (May and June 2000), there were five VOC detected during both sampling rounds: 1,2-DCB, 1,3-DCB, 1,4-DCB, benzene, and CB. Only benzene and CB were detected above the respective GWQC. Benzene was detected at 2.60 ug/L and 3.46 ug/L, respectively, which exceeded the GWQC of 1.0 ug/L. CB was detected at 43.73 ug/L and 49.92 ug/L, respectively, which exceeded the GWQC of 4.0 ug/L. Both benzene and CB are identified as COC.

Four SVOC were detected during both sampling rounds: 1,3-DCB, 1,4-DCB, 2-methylnaphthalene, and Bis(2-Ethylhexyl)phthalate. None of the four SVOC was detected above their respective GWQC. There were no pesticides or PCB detected during the two sampling events.

A total of 16 metals were detected during the two sampling rounds. Of the 16 metals detected, 13 metals (aluminum, barium, calcium, chromium, cobalt, copper, magnesium, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Three metals (iron, lead, and manganese) were detected above their respective GWQC, but none is identified as a COC.

Iron was detected in both sampling events at 57,700 ug/L and 63,600 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L, but not the MBC of 431,000 ug/L. Manganese was detected in both sampling events at 680 ug/L and 643 ug/L, which exceeded the GWQC for manganese of 50 ug/L and the MBC of 331 ug/L. However, based upon the frequency of occurrence and the magnitude of the detections at this monitoring well and adjacent locations, iron and manganese are not identified as a COC.

Lead was detected in both sampling events at 12.9 ug/L and 10.1 ug/L, which exceeded the GWQC for lead of 10 ug/L. MW-21 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were 2.28 ug/L and 10.7 ug/L, respectively. While detected slightly above the GWQC, the reported results for lead are consistent and very close to the GWQC. Lead is not identified as a COC. (These analytical results will be submitted to the NJDEP under separate cover at a later date.)

Monitoring Well MW-22

During the two rounds of groundwater sampling conducted to-date at MW-22 (May and June 2000), tert-butyl alcohol was the only VOC detected. Tert-butyl alcohol was detected during both sampling events at 373.98 ug/L and 462.08 ug/L. There is no established GWQC for tert-butyl alcohol. There were no SVOC, pesticides, or PCB detected during the two sampling events.

A total of 13 metals were detected during the two sampling rounds. Of the 13 metals detected, 11 metals (aluminum, barium, calcium, chromium, copper, magnesium, nickel, potassium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Two metals (iron and manganese) were detected above their respective GWQC, but neither is identified as a COC.

Iron was detected in both sampling events at 36,100 ug/L and 33,500 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L. However, the detections for iron were both below the respective MBC of 431,000 ug/L. Manganese was detected in both sampling events at 267 ug/L and 295 ug/L, which exceeded the GWQC for of 50 ug/L. However, the detections for manganese were also below the respective MBC of 331 ug/L. Iron and manganese are not identified as COC.

Monitoring Well MW-23

During the two rounds of groundwater sampling conducted to-date at MW-23 (May and June 2000), there were three VOC detected during both sampling rounds: 1,4-DCB, benzene, and CB. Only benzene and CB were detected above the respective GWQC. Benzene was detected at 5.92 ug/L and 5.17 ug/L, respectively, which exceeded the GWQC of 1.0 ug/L. CB was detected at 44.43 ug/L and 37.26 ug/L, respectively, which exceeded the GWQC of 4.0 ug/L. Both benzene and CB are identified as COC.

Four SVOC were detected during both sampling rounds: 1,4-DCB, 2-methylnaphthalene, bis(2-ethylhexyl)phthalate, and n-nitrosodiphenylamine. None of the four SVOC were detected above

their respective GWQC. There were no pesticides or PCB detected during the two sampling events.

A total of 16 metals were detected during the two sampling rounds. Of the 16 metals detected, 13 metals (aluminum, barium, calcium, chromium, cobalt, copper, magnesium, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Three metals (iron, lead, and manganese) were detected above their respective GWQC, but none is identified as COC.

Iron was detected in both sampling events at 76,900 ug/L and 61,100 ug/L, respectively, which exceeded the GWQC for iron of 300 ug/L, but not the MBC of 431,000 ug/L. Manganese was detected in both sampling events at 361 ug/L and 292 ug/L, which exceeded the GWQC for manganese of 50 ug/L and in the first sampling event, the MBC of 331 ug/L. However, given the frequency of occurrence and the magnitude of the detections at this location and in adjacent wells, iron and manganese are not identified as a COC.

Lead was detected in one sampling event at 39.3 ug/L, which exceeded the GWQC for lead of 10 ug/L. However, MW-23 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were both ND. (These analytical results will be submitted to the NJDEP under separate cover at a later date.)

Monitoring Well MW-24

During the two rounds of groundwater sampling conducted to-date at MW-24 (May and June 2000), there were three VOC detected during both sampling rounds: 1,4-DCB, benzene, and CB. Only benzene and CB were detected above the respective GWQC. Benzene was detected at 1.37 ug/L and 1.75 ug/L, respectively, which exceeded the GWQC of 1.0 ug/L. CB was detected at 5.21 ug/L and 5.67 ug/L, respectively, which exceeded the GWQC of 4.0 ug/L. Both benzene and CB are identified as COC.

Four SVOC were detected during both sampling rounds: 1,4-DCB, 2-methylnaphthalene, bis(2-ethylhexyl)phthalate. In addition, acenaphthene, fluorene, and n-nitrosodiphenylamine were each detected during one sampling round. None of the seven total SVOC was detected above their respective GWQC. There were no pesticides or PCB detected during the two sampling events.

A total of 17 metals were detected during the two sampling rounds. Of the 17 metals detected, 13 metals (barium, cadmium, calcium, chromium, cobalt, copper, magnesium, nickel, potassium, selenium, sodium, vanadium, and zinc) were measured at concentrations below their respective GWQC or no GWQC existed for the detected metal. Four metals (aluminum, iron, lead, and manganese) were detected above their respective GWQC, but none is identified as a COC.

Aluminum was detected during both sampling events and during May at 264 ug/L, which exceeded the GWQC of 200 ug/L, but not the MBC of 121,000 ug/L. Iron was detected in both sampling events at 60,300 ug/L and 56,100 ug/L, respectively, which exceed the GWQC for iron of 300 ug/L, but not the MBC of 431,000 ug/L. Manganese was detected in both sampling

events at 748 ug/L and 682 ug/L, which exceeded the GWQC for manganese of 50 ug/L and the MBC of 331 ug/L. However, given the frequency of occurrence and the magnitude of the detections at this location and in adjacent wells, aluminum, iron and manganese are not identified as a COC.

Lead was detected in one sampling event at 49.5 ug/L, which exceeded the GWQC of 10 ug/L. However, MW-24 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were ND and 6.15 ug/L, respectively. (These analytical results will be submitted to the NJDEP under separate cover at a later date.)

Summary of Groundwater Investigation

Historically, separate phase hydrocarbons were not reported in any of the groundwater monitoring wells at the M-2 Landfill. In summarizing the Quarterly Monitoring Program, VOC were detected in 16 of the monitoring wells. Benzene and CB were the only VOC with detected concentrations that exceeded the respective GWQC. These findings appear to be consistent for the shallow fill material (i.e., depths ranging from 7 feet to 20 feet bgs) with the findings presented in Subsection 3.2.2. However, in the four deeper wells (MW-11, MW-12, MW-19, and MW-20), only benzene has been detected, and only once at a concentration that exceeded the GWQC (MW-11). However, due to the upward hydraulic gradient in the MW-11 area, no deeper migration of the benzene is expected.

Benzene and CB are considered to be COC. **Figure 9** shows the analytical results for benzene and CB for each sampling round. In addition, benzene and CB detections above the respective GWQC have been "highlighted" on **Figure 9**.

SVOC were detected in eleven of the monitoring wells, but only one detection for bis(2-ethylhexyl)phthalate at MW05 (out of 7 sampling rounds) exceeded the respective GWQC. SVOC are not identified as COC.

Pesticides were detected in four monitoring wells (MW-01, MW-03, MW-06, and MW-09). The detections were infrequent and none of the detections exceeded the respective GWQC. Pesticides, either individually or collectively, are not identified as COC.

PCB were detected in two monitoring wells (MW-06 and MW-09) at concentrations that exceeded the respective GWQC. The findings of the PCB Investigation presented in Subsection 3.2.1 noted the detection of PCB in a number of groundwater samples collected from GeoProbe® borings and, in particular, borings located in the vicinity of MW-23 (which is also in the vicinity of MW-09). The high turbidity and sediment content of the groundwater samples collected from GeoProbe® borings were shown to be the primary factor affecting the detection of PCB.

During evaluation of the Quarterly Groundwater Monitoring Program results, the DPW decided to determine whether the PCB detected in the groundwater samples from MW-6 and MW-9 were actually in the groundwater or adhering to entrained sediment that may have been collected with the water sample. Therefore, the DPW proposed to the NJDEP to sample these wells using a low

flow sampling technique. This technique essentially purges the well at a low purge rate to ensure laminar flow, minimal disturbance of the water column, and minimal contact with the atmosphere. The well is purged until indicator parameters such as conductance, pH, and dissolved oxygen content are stable. The collected sample is, therefore, believed to be more closely representative of actual aquifer conditions. A copy of the low flow-sampling plan and analytical results are provided in **Appendix C**.

Monitoring wells MW-6 and MW-9 were sampled twice, on January 5 and on January 27, 2000, using low flow techniques. The samples were analyzed for PCB and metals. The analytical results from the low flow sampling reported no PCB detections. Furthermore, PCB have not been detected at MW-11 or MW-23. MW-23 is screened at 5 – 20 ft bgs, which is at a similar depth as the groundwater samples collected from the boring locations. Well MW-11 is screened deeper within the fill material at 30 – 50 ft bgs. Based on these findings, in addition to the low solubility and immobility of these compounds, PCB are not identified as COC.

A total of nine metals have been detected above their respective GWQC during performance of the Quarterly Groundwater Monitoring Program at the M-2 Landfill: aluminum, antimony, arsenic, cadmium, chromium, iron, lead, manganese, and silver. Aluminum has been detected in 14 wells above the GWQC of 200 ug/L (MW-01, 04, 05, 06, 07, 08, 09, 10, 14, 15, 17, 19, 20,and 24). Although aluminum concentrations exceeded the GWQC, the reported concentrations did not exceed the MBC for aluminum of 121,000 ug/L. Similarly, iron has been detected in all 24 wells above the GWQC of 300 ug/L; however, no detections exceeded the MBC for iron of 431,000 ug/L. In addition, manganese was detected in 19 wells above the GWQC of 50 ug/L (MW-01, 02, 03, 04, 06, 07, 08, 09, 10, 13, 14, 15, 16, 18, 19, 21, 22, 23, and 24), with some of the detections exceeding the MBC of 331 ug/L. As previously discussed, aluminum, manganese, and iron are considered to be natural constituents of the native soils at Fort Monmouth, and based on the information presented, aluminum, iron, and manganese are not identified as COC.

Antimony was detected above the GWQC of 20 ug/L only at MW-06 at 566 ug/L during one sampling event (March 1999). There was only one previously reported detection for antimony at MW-06, which was 3.76 ug/L observed during the November 1998 sampling event. The reported results for antimony for the other five sampling rounds were ND. The analytical results of the low flow sampling performed at MW-06 (summarized below) reported antimony at 5 ug/L, i.e., below the GWQC. Antimony is not identified as a COC.

Arsenic was detected above the GWQC of 8 ug/L at MW-05 during one sampling round - 8.86 ug/L (November 1998), at MW-06 during one sampling round - 16.5 ug/L (November 1998), and at MW-09 during two sampling rounds -13.3 ug/L (November 1998) and 22.1 ug/L (June 1999). The detection at MW-05 marginally exceeded the GWQC and the reported results for arsenic for the subsequent five sampling rounds have not exceeded the GWQC. The detection in November 1998 that exceeded the GWQC at MW-06 has been followed by five sampling rounds having only one reported detection for arsenic at 5.6 ug/L, i.e., below the GWQC. At MW-06, the three sampling rounds since the June 1999 detection have reported arsenic at 3.9 ug/L, 5.86 ug/L, and ND, all of which were below the GWQC. In addition, the analytical results of the low

flow sampling performed at MW-06 (summarized below) reported arsenic at ND. Arsenic is not identified as a COC.

Cadmium was detected in three monitoring wells (MW-01, 08, and 09) above the GWQC of 4.0 ug/L. At MW-01, one detection at 6.23 ug/L during one sampling round (November 1998) exceeded the GWQC. The five subsequent sampling rounds have not exceeded the GWQC. Similarly at MW-08, one detection at 4.14 ug/L during one sampling round (June 1999) slightly exceeded the GWQC. The three subsequent sampling rounds at MW-08 have not exceeded the GWQC. At MW-09, cadmium was detected in exceedence of the GWQC during three sampling rounds ranging from 4.49 - 15.2 ug/L. However, the analytical results of the low flow sampling performed at MW-09 reported cadmium at ND. Cadmium is not identified as a COC.

Fort Monmouth Main Post – Comparison of Quarterly Groundwater Sampling and Low Flow Sampling at MW-06

Metals (Total)	Range of Quarterly Groundwater Sampling Results MW-06 (ug/L)	Result of Low Flow Sampling Performed 6 January 2000 (ug/L)	NJDEP Groundwater Quality Criteria (ug/L)
Aluminum	**616 – 10,300**	ND	200
Antimony	ND – **566**	5.0	20
Arsenic	ND – **16.5**	ND	8
Barium	90.3 - 189	65.5	2,000
Beryllium	ND – 1.52	ND	20
Cadmium	ND – 3.28	ND	4
Calcium	39,300 – 54,000	43,900	NLE
Chromium	6.4 – **16,000**	1.2	100
Cobalt	0.579 – 29.3	ND	NLE
Copper	ND – 55.1	60.0	1,000
Iron	**16,500 – 50,700**	**11,600**	300
Lead	ND – **90.5**	ND	10
Magnesium	4,710 - 14,100	5,300	NLE
Manganese	**52.4 – 247**	**53.9**	50
Mercury	ND – 0.47	0.17	2
Nickel	ND – 18.9	2.00	100
Potassium	5,490 – 15,100	6,160	NLE
Selenium*	ND	ND	50
Silver	ND – 3.83	10.0	20
Sodium	4,540 – 8,620	8,180	50,000
Thallium	ND – 6.7	ND	10
Vanadium	3.53 – 46.6	ND	NLE
Zinc	11.3 – 392	13.0	5,000

ND – Not Detected.

NLE – No Limit Established.
* Selenium has not been detected in any sampling rounds to-date at MW-06.

Chromium was detected in two monitoring wells above the GWQC of 100 ug/L, MW-06 and MW-09. There were two sampling rounds with detections for chromium above the GWQC at MW-06, 105 ug/L in November 1998 and 16,000 ug/L in March 2000. There were also two sampling rounds with detections for chromium above the GWQC at MW-09, 116 ug/L in November 1998 and 309 ug/L in June 1999. At MW-06, the November 1998 detection only marginally exceeded the GWQC and the March 2000 detection can be considered an anomaly given the average of the previous six sampling rounds – 26 ug/L. At MW-09, the last three sampling rounds have all reported detections below the GWQC. In addition, the results of the low flow sampling at MW-06 and MW-09 for chromium were below the GWQC at 1.2 ug/L and 67.2 ug/L, respectively. Chromium is not identified as a COC.

Lead has been detected at 12 monitoring wells above the GWQC of 10 ug/L (MW-01, 03, 05, 06, 07, 08, 09, 11, 15, 21, 23, and 24). At MW-01, the detection at 11.0 ug/L reported for the October 1999 sampling round slightly exceeded the GWQC. The subsequent nine sampling rounds reported seven rounds at ND and two rounds with detections (6.95 ug/L and 4.10 ug/L) that were both below the GWQC. At MW-03, the detection at 13.0 ug/L reported for the October 1999 sampling round marginally exceeded the GWQC. The subsequent nine sampling rounds reported either ND (4 rounds) or detections that were below the GWQC (5 rounds). At MW-05 the detection at 15.3 ug/L reported for the November 1998 sampling round exceeded the GWQC. Since the November 1998 sampling round, the five subsequent reported detections for lead have all been below the GWQC. At MW-06, the detections reported for lead from the first three sampling rounds, 13.6 ug/L, 22.4 ug/L, and 90.5 ug/L, respectively, exceeded the GWQC of 10 ug/L. However, the reported results for lead over the four subsequent sampling rounds have all been below the GWQC or ND. At MW-07, the detections from the first two sampling rounds, 13.0 ug/L in October 1998 and 16.4 ug/L in November 1998 exceeded the GWQC for lead. Since the first two sampling rounds, the reported results for lead over the five subsequent sampling rounds have either been ND (2 rounds) or the detections were below the GWQC (3 rounds). At MW-08, four of the reported detections for lead exceeded the GWQC. However, the lead results reported from the last two sampling rounds (October 1999 and March 2000) have both been below the GWQC. At MW-09, six of the reported detections for lead exceeded the GWQC. As previously discussed, the results of the low flow sampling performed at MW-09 for lead was ND, showing that the reported lead concentrations were most likely attributable to sediment entrained in the samples during the sampling event and not representative of actual groundwater conditions. Lead was detected at MW-11 in the June sampling event at 84.5 ug/L, which was above the GWQC. MW-11 has been sampled during two sampling events, September and December 2000, and the reported results for lead were ND. (These analytical results will be submitted to the NJDEP under separate cover at a later date.) Lead was detected in both sampling events (May and June 2000) at MW-15 at 14.0 ug/L and 41.5 ug/L, respectively, which exceeded the GWQC. MW-15 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were ND and 6.57 ug/L, respectively, which were both below the GWQC. Lead was also detected in both the May and June 2000 sampling events at MW-21 at 12.9 ug/L and 10.1 ug/L, respectively, which slightly exceeded the GWQC. MW-21 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were 2.28 ug/L and 10.7 ug/L,

respectively. While the December result was slightly above the GWQC, the reported results for lead have remained consistent. Lead was detected in the June 2000 sampling event at MW-23 at 39.3 ug/L, which exceeded the GWQC. MW-23 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were both ND.

Lead was detected at MW-24 in the May 2000 sampling event at 49.5 ug/L, which exceeded the GWQC. MW-24 has been sampled during two subsequent sampling events, September and December 2000, and the reported results for lead were ND and 6.15 ug/L, respectively. Lead is not identified as a COC.

Silver was detected at MW-02 and MW-03 above the GWQC of 20 ug/L. At MW-02, silver was detected only during the first sampling round at 41.0 ug/L. This detection is most likely attributable to a laboratory error since the laboratory calibration blank reported a result greater than the GWQC for silver. Silver has not been detected again since the first sampling round at MW-02. At MW-03, silver was detected only during the first two sampling rounds at 36.0 ug/L and 9,170 ug/L, respectively. The detection for the first sampling round (36.0 ug/L) was attributable to a laboratory error since the respective laboratory calibration blank reported a result greater than the GWQC for silver. It is also likely that the detection reported during the second sampling round (9,170 ug/L) is either attributable to a laboratory error, since this result is an order of magnitude greater than any other reported result for silver at the M-2 Landfill, or an anomaly, since silver has not been detected again at MW-03 since the first two sampling rounds. Silver is not identified as a COC.

The analytical results have been presented and evaluated for the nine metals that were detected above their respective GWQC during performance of the Quarterly Groundwater Monitoring Program at the M-2 Landfill: aluminum, antimony, arsenic, cadmium, chromium, iron, lead, manganese, and silver. Overall, the results of the low flow sampling shown for MW-06 and MW-09 suggest that many of the metals are likely attributable to sediment entrained in the groundwater samples during the regular sampling events, which are subsequently dissolved in the groundwater in the sample container as the result of acidification (preservation) of the sample. Such conditions are not representative of actual formation groundwater conditions.

In addition to the information presented above, comparison of the groundwater analytical data with the surface water data collected from Mill Creek (adjacent to the landfill) indicates that the groundwater beneath the landfill is not affecting surface water quality. In summary, no metals are identified as COC at the M-2 Landfill.

3.2.5 Aquifer Test Results - Slug Test and Pump Test

To determine the aquifer characteristics of the shallow saturated zone beneath the M-2 Landfill, slug testing was performed on monitoring wells MW-12, MW-13, MW-18, MW-20 and MW-23 and a pump test was performed on MW-19. The aquifer test results are provided in **Appendix D**.

Analysis of the water level data collected during the slug tests indicates the hydraulic conductivity of the subsurface materials is low, ranging from 1.24E -06 ft/day to 5.14E-06 ft/day and averaging 2.50E-06 ft/day.

A five-hour pumping test was conducted in MW-19 (total depth 50 ft). The groundwater levels in the pumped well and a nearby well, MW-24 (total depth 20 ft), were monitored during the test. The initial pumping rate was 3 gallons per minute (gpm). After five hours, the rate was increased to 6 gpm and then to 8 gpm, but neither pumping rate could be sustained. As would be expected, the analysis of the pump test data indicates a higher conductivity than the slug tests. Analysis of data from MW-24 establishes a hydraulic conductivity of 1.2 ft/day (transmissivity = 381 gallons/day/foot), while analysis of data from MW-19 estimates a hydraulic conductivity of 0.2 to 0.4 ft/day (transmissivity = 72 to 135 gallons/day/foot). The observed values for the hydraulic conductivity are to be expected given the silty, clayey, sandy nature of the subsurface materials beneath the M-2 Landfill.

The aquifer storage coefficients derived from the pumping test were generally less than 1E-06 with one exception. One analytical method (Hantush method for leaky aquifers) yielded a storage coefficient of 1.0E-02. This very low storage coefficients suggest that the saturated zone beneath the landfill has little effective porosity.

The hydraulic conductivities from the pump test are more realistic than the slug tests because they are based on data collected over a longer period of time and during a period of sustained pumping. The hydraulic conductivity in MW-24 may be more representative of the shallow (less than 20 ft) saturated zone while the hydraulic conductivity in MW-19 is an approximate representation of the deeper (50 ft) saturated zone. The shallow fill material, as expected, is more permeable than the native glauconitic sands underlying the landfill.

3.2.6 Surface Water Sampling

Since October 1996, stream (surface water) samples have been collected quarterly and then monthly from a total of 22 locations on Fort Monmouth associated with Parkers Creek, Lafetra Creek and Mill Creek. The M-2 Landfill is located on the south bank of Mill Creek and three of the sampling locations are located in the vicinity of the landfill. The three sample locations, which are a part of the long-term surface water monitoring program, include: Site 13 (upstream of the landfill); Site 15 (upstream of the landfill), and Site 16 (downstream of the landfill). In addition, two new sample locations have recently been added to the program, specifically: Site 23 (located on the upstream edge of the landfill) and Site 24 (located on the downstream edge of the landfill). **Figure 10** shows the five sampling locations.

The collected surface-water samples have been analyzed for VOC, pH, ammonia, nitrates, phosphate, sulfate, dissolved oxygen, coliform, and salinity. Laboratory results for VOC for the five locations are summarized on **Table 6**. Sites 13, 15, and 16 include monthly/quarterly analytical results since 1996, while Sites 23 and 24 were only sampled recently in June 2000.

A total of 18 surface-water samples were collected from Site 13 since 1996. Methylene chloride was detected above the MDL and the respective SWQC of 2.49 ug/L in the first three sampling events. Detected values ranged from 2.59 to 3.76 ug/L. In two of the sampling events, methylene chloride was also detected in the method blank. PCE was detected above the MDL and SWQC of 0.39 ug/L in the last three sampling events, ranging from 3.94 to 6.92 ug/L.

A total of 19 surface-water samples were collected from Site 15 since 1996. Acetone and methyl-tert-butyl ether were detected above the MDL in one sampling event at 4.22 ug/L and 2.38 ug/L, respectively. The compound cis-1,2-Dichloroethene was detected above the MDL in ten sampling events, ranging from 1.22 to 5.53 ug/L. SWQC do not exist for these three VOC. Methylene chloride was detected above the MDL and the respective SWQC of 2.49 ug/L in the first four sampling events, ranging from 2.68 to 5.51 ug/L. In three of the sampling events, methylene chloride was also detected in the method blank. PCE was detected in all sampling events above the MDL and the SWQC of 0.39 ug/L, ranging from 2.61 to 10.38 ug/L. TCE was detected in 12 sampling events above the MDL, and in 11 sampling events above the SWQC of 1.09 ug/L, ranging from 1.03 ug/L to 2.58 ug/L.

A total of 18 surface-water samples were collected from Site 16 since 1996. The compound cis-1,2-Dichloroethene was detected above the MDL in ten sampling events, ranging from 1.27 to 3.56 ug/L. Methyl-tert-butyl ether was detected above the MDL in one sampling event at 2.33 ug/L. SWQC do not exist for either of these two VOC. Methylene chloride was detected above the MDL and the respective SWQC of 2.49 ug/L in the first three sampling events, ranging from 3.01 to 4.65 ug/L. In one of the sampling events, methylene chloride was also detected in the method blank. PCE was detected in all sampling events above the MDL and the SWQC of 0.39 ug/L, ranging from 1.48 to 8.20 ug/L. TCE was detected in eight of the sampling events above the MDL and in seven sampling events above the SWQC of 1.09 ug/L, ranging from 1.00 ug/L to 2.25 ug/L.

In summarizing the surface-water sampling data, PCE and TCE were consistently detected above the MDL and the respective SWQC at two of the primary sampling locations (Sites 15 and 16), and at Site 13 during the last three sampling events. PCE was also detected at both Sites 23 and 24 during the June 2000 sampling event. Acetone, cis-1,2-Dichloroethene, and methyl-tert-butyl ether were infrequently detected and have no SWQC. They are not identified as COC.

Methylene chloride was detected in the stream samples for Sites 13, 15, and 16 above the MDL and the SWQC. However, in each case, methylene chloride was also detected in the method blank. Methylene chloride is a known laboratory contaminant and is not a COC.

PCE and TCE are considered to be COC, however, both VOC have been consistently detected in the surface water samples collected from upstream of the landfill (Sites 13 and 15), and then again at Site 23 located on the upstream edge of the landfill. It is the DPW's contention that the concentrations of PCE and TCE are from a source upgradient of the M-2 Landfill and beyond the boundary of Fort Monmouth.

3.2.7 PCB Sediment and Surface Water Sampling

On April 14, 2000, sediment samples from Mill Creek were collected by TVS personnel from 12 locations along the border of the M-2 Landfill to evaluate the potential impact to the stream from the PCB detected in the soils and shallow groundwater of the landfill. A total of 24 sediment samples and two duplicates were collected at depths of 0 to 0.5 ft and 0.5 to 1.0 ft below the stream bottom and analyzed for Total PCB. The analytical results are presented in **Table 7** and the sample locations are shown on **Figure 11**. Sample Location No. 11 and one duplicate sample (presumably collected at Sample Location No. 12) detected concentrations of PCB (Arochlor 1254 at 0.047 mg/Kg and 0.055 mg/Kg, respectively). No other PCB were detected. These concentrations are well below the Lowest Effect Level of 0.060 mg/Kg for PCB listed in the NJDEP Guidance for Sediment Quality Evaluations (November 1998).

In response to the detection of PCB in one sediment sample, two rounds of surface water sampling were conducted in May and June 2000 at three locations in Mill Creek. Each sampling round was performed at both high tide and low tide. Round 1 – high tide was collected on 31 May at approximately 8:30 AM, Round 1 – low tide was collected on 1 June at approximately 3 PM, Round 2 – low tide was collected on 8 June at approximately 11AM, and Round 2- high tide was collected on 14 June at approximately 9AM. The samples were collected at the following standard Fort Monmouth surface water sampling locations (refer to **Figure 10**): No. 15 (upstream of the landfill); No. 24 (downstream of the landfill), and at No. 23, which was downgradient of sediment Sampling Location No. 11 (the location at which the PCB was detected in stream sediments). The samples were analyzed for Total PCB. The analytical results are presented in **Table 8.** There were no detections of PCB in either surface-water sampling round.

3.2.8 Sensitive Receptors/Well Survey

Searches were conducted using various databases and historical information to identify receptors and groundwater wells that may be potentially affected by the M-2 Landfill. An Offsite Receptor Report (dated 27 June 2000) was prepared for the M-2 Landfill by Environmental Data Resources, Inc. (EDR). In addition, a search of the comprehensive well database maintained by the NJDEP – Well Permitting and Regulations Section of the Bureau of Water Allocation was performed. The search was performed for a one mile radius surrounding the center point of the M-2 Landfill. A copy of the sensitive receptor survey is provided in **Appendix E** and a copy of the Well Search Summary is provided in **Appendix F**.

The results of the well search summary identified 294 database records within a one-mile radius of the M-2 Landfill, and include the following relevant wells:

- Monitoring Wells: 212 monitoring wells are identified within one mile of the M-2 Landfill. The well depths ranged from 12 to 80 ft.
- Domestic Wells: 28 domestic wells are identified within one mile of the M-2 Landfill. The well depths ranged from 40 to 230 ft.
- Irrigation Wells – 8 irrigation wells are identified within one mile of the M-2 Landfill. The wells ranged from 20 – 200 ft.

- Public Supply Wells – No public supply, public non-community, or non-public [supply] wells are identified within one mile of the M-2 Landfill.

Regarding potential human and ecological receptors, the most obvious sensitive receptor relative to the M-2 Landfill is Mill Creek, which flows along the north side of the landfill. The data base searches also indicated that two schools were located within one-half to one-mile south-southeast of the landfill. In the case of the M-2 Landfill, potential receptors are not expected to be impacted because of the following:

1. The site is located on an Army-controlled installation and is surrounded on three sides with a six-foot high chain link fence and on the fourth side by Mill Creek, which restricts access to the site.
2. Analyses of groundwater samples indicate that benzene and CB are present in the shallow groundwater in the landfill at concentrations exceeding the GWQC. In addition, benzene was detected at concentrations exceeding the GWQC in groundwater samples collected from one monitoring well (MW-11) drilled deeper into the aquifer (i.e., 50 ft bgs). However, benzene and CB have not been detected in Mill Creek. Further, the results of the groundwater-monitoring program show that VOC concentrations have decreased over time and have not migrated off-site. Based upon the findings of the well search, no public supply, public non-community, or non public [supply] wells are identified within one mile of the M-2 Landfill. Further, there are no domestic, irrigation, industrial, or supply wells existing within the boundaries of the M-2 Landfill, nor will any be installed in the future. Since no groundwater use is occurring or is anticipated to occur, the groundwater beneath the M-2 Landfill is not considered to be a potential receptor pathway.
3. Surface water samples from Mill Creek have indicated the presence of PCE and TCE in concentrations slightly above the GWQC. However, these contaminants are presumed to originate from a separate source upgradient of the M-2 Landfill and beyond the boundary of Fort Monmouth.
4. There are no expected concerns regarding direct human exposure to impacted soils. The cover afforded by the M-2 Landfill is expected to be adequate to continue to provide a barrier to direct human exposure. Additionally, since closure the past 30+ years have seen the growth and stabilization of vegetation (i.e., grass, trees, brush) on the M-2 Landfill. The current institutional controls (i.e., fencing) will be maintained to limit direct contact with the site and periodic inspections of the fencing and landfill cover will be continued.
5. In addition, the DPW will incorporate a document equivalent to a DER into the Fort Monmouth Installation Master Plan (for soils containing PCB) to restrict site development and future use of the M-2 Landfill site, and recognize the planned long-term monitoring of this area.

3.3 SUMMARY AND SITE CONCEPTUAL MODEL

The M-2 Landfill consists of a flat to gently sloping surface cover composed of vegetated soil. This earthen cover is stable, approximately 0 to 2 ft thick, and has been generally undisturbed for

over 30 years. Beneath the earthen cover is fill material consisting of waste mixed with organic material, sand, silt and clay. The fill material ranges in thickness from approximately 4 ft to approximately 10 ft. Beneath the fill is the natural soil consisting of silty clays and fine sand. A generalized geologic cross-section of the landfill is depicted in **Figure 12**.

Groundwater is encountered at depths of approximately 8 ft below the surface of the landfill. The groundwater is unconfined (water table conditions) and flows north-northwest towards Mill Creek, which flows eastward into Parkers Creek. Aquifer testing, using monitoring wells installed in the landfill, indicated that the hydraulic conductivity of the saturated materials is low and the groundwater storage capacity of the materials is very low. Consequently, groundwater movement towards Mill Creek is slow.

Sampling of the surface and subsurface soils, groundwater and surface water at the M-2 Landfill has delineated the degree and extent of potential contaminants. The surface cover soils (0 to 2 ft) had seven SVOC at concentrations above the RDCSCC randomly scattered among 12 locations across the landfill. The surface cover soils had three pesticides and four PCB compounds in concentrations above the RDCSCC scattered among 11 locations. Seven metals scattered among 19 borings exceeded the RDCSCC in the cover soils. No exceedences of the RDCSCC for VOC were detected in the cover soils. Although exceedences of NJDEP RDCSCC are identified in the near surface soils for SVOC, pesticides/PCB, and metals within the landfill, evaluation of the analytical results did not define a “source area” or level of contamination that necessitated the identification and evaluation of potential remedial actions. Either the specific calculated compliance average was below the respective RDCSCC, the exceedence was considered marginal, or the exceedence was considered an isolated location or a de minimus quantity. No further action is recommended for the near surface soils. However, to address the PCB and other contaminants detected in the near surface soils, the DPW will incorporate a document equivalent to a DER into the Fort Monmouth Master Plan.

Analyses of deeper soils in the landfill indicated that only PCB in a few scattered locations were detected at concentrations above the RDCSCC. No other compound exceedences were detected in the deeper soils. The current institutional controls in place at the M-2 Landfill (i.e., the site is located on an Army-controlled installation, and is surrounded on three sides with a six-foot high chain link fence and on the fourth side by Mill Creek restrict access to the site. To further address the PCB concentrations detected in soil at the M-2 Landfill, the DPW will incorporate a document equivalent to a DER into the Fort Monmouth Installation Master Plan for soils containing PCB to restrict site development and future use of the M-2 Landfill site, and recognize the planned long-term monitoring of this area.

Surface-water samples from Mill Creek indicated the presence of PCE and TCE in concentrations slightly above the GWQC. These compounds were not detected in the groundwater beneath the M-2 Landfill. It is the DPW’s contention that the concentrations of PCE and TCE are from a source upgradient of the M-2 Landfill and beyond the boundary of Fort Monmouth.

Analyses of numerous groundwater samples indicate that benzene and CB are present in the shallow groundwater in the landfill at concentrations exceeding the GWQC. Benzene was detected in a single groundwater sample collected from a well drilled deeper into the aquifer. However, a vertically upward hydraulic gradient was calculated, which suggests that further vertical migration in the aquifer is unlikely.

Overall, the results of the low flow sampling suggest that the PCB and many of the metals detected in the groundwater are likely attributable to sediment entrained in the samples during the regular sampling events, which are subsequently dissolved in the groundwater in the sample container as the result of acidification (preservation) of the sample. Such conditions are not representative of actual formation groundwater conditions. These contaminants are also regarded as highly immobile and insoluble.

Benzene and CB are not identified in Mill Creek, and there are no exceedences of the RDCSCC for these compounds in the soils. The distribution of benzene and CB in the groundwater may be indicative of a combination of biodegradation and retardation (due in part to the low hydraulic conductivity) that limit or prevent migration to Mill Creek. It is reasonable to assume that the concentrations of benzene and CB observed in the shallow groundwater may represent residual, equilibrium concentrations. With regard to remediation, the shallow groundwater is the only area of concern that may need to be addressed at the M-2 Landfill. The benzene detected in deep well MW-11 is not of long-term concern because the hydraulic gradient around MW-11 is upward; thereby, containing the benzene impacted groundwater within the shallow aquifer.

3.4 CLASSIFICATION EXCEPTION AREA

The findings of the RIR show that shallow groundwater within the defined boundary of the M-2 Landfill exceeds the respective GWQC for benzene and CB. The New Jersey Ground Water Quality Standards (GWQS), N.J.A.C. 7:9-6, provide the basis for the protection of ambient groundwater quality of the state. The GWQS recognize the different natural utility of groundwater in various parts of the state and classify groundwater into Classification Areas according to a combination of natural characteristics and actual or potential uses.

The GWQS allow the NJDEP to designate areas of exception to strict application of the GWQS in certain specific situations. A Classification Exception Area (CEA) is established to provide notice that the constituent standards for a given aquifer classification are not or will not be met in a localized area due to natural water quality or anthropogenic influences, and that designated aquifer uses are suspended in the affected area for the term of the CEA. The NJDEP may designate a CEA only when constituent standards are not or will not be met due to:

- natural groundwater quality;
- localized effects of a permitted discharge (e.g., effluent limits above the constituent standards with discharge outside the plume/capture zone);
- part of a pollution remedy conducted pursuant to an Administrative Consent Order (ACO) or other NJDEP oversight mechanism or program; or,

- an Alternate Concentration Limit (ACL) approved under the New Jersey Pollutant Discharge Elimination System (NJPDES).

The intent of a CEA is to restrict uses of the aquifer until the applicable GWQS are met. CEAs are typically of limited duration and are related to the term of a permit approval or estimated time for completion of a remediation. To obtain a CEA designation, three elements must be specified:

- CEA boundaries.
- Contaminants of Concern (COC).
- Duration of the Exception.

The boundaries of a proposed CEA area must meet several requirements. They must:

- Include only the area affected by the remediation program.
- Delineate the horizontal and vertical extent of current and future plume(s).
- Include an identification of all streams, roads, natural and man-made borders, and lot and block numbers of impacted properties.
- Identify all relevant geologic formations.
- Be submitted in an electronic format map compatible with NJ GIS requirements.

All contaminants for which a CEA is being sought must be identified as part of the CEA application. Both primary contaminants and breakdown products that may exceed GWQS must be identified. The duration of the remediation program must also be estimated although an indeterminate duration may be applicable in the case of inorganic species.

A Proposed CEA designation has been generated for the M-2 Landfill. The report is provided in **Appendix H**. The Proposal encompasses the required information summarized above and has been completed in accordance with the current NJDEP guidance, specifically, the procedures described in the *Final Guidance on Designation of CEAs and the Regulatory Requirements*, N.J.A.C. 7:9-6.6, published November 1998.

The data from RI indicates that two VOC analytes, benzene and CB, will require an exception to the GWQC because they are consistently present at concentrations above the GWQC in one or more wells. Metals at concentrations above GWQC will not be considered COC due to their immobility (high K_d, implicit retardation), as well as the soil chemistry and natural background conditions at Fort Monmouth, and the results of the low flow sampling performed and trends of detection reported in the RIR. The results of the groundwater-monitoring program show that VOC concentrations have decreased over time and have not migrated off-site. The fact that there is no increase in concentrations of the contaminants detected above the GWQC with time indicates that no new sources of contamination have impacted the shallow groundwater.

Based upon the findings of the well search (Subsection 3.2.8), no public supply, public non-community, or non-public [supply] wells are identified within one mile of the M-2 Landfill. Further, there are no domestic, irrigation, industrial, or supply wells existing within the

boundaries of the M-2 Landfill, nor will any be installed in the future (the DPW will incorporate a document equivalent to a DER into the Fort Monmouth Installation Master Plan to restrict site development and future use of the M-2 Landfill site, and recognize the planned long-term monitoring of this area). Since no groundwater use is occurring or is anticipated to occur, the shallow groundwater beneath the M-2 Landfill is not considered a groundwater use area. A CEA is also proposed to document the quality of the groundwater in the vicinity of the site, and limit or prevent unauthorized uses until such time as the benzene and CB have declined to concentrations below the GWQC or site cleanup criteria.

The horizontal and vertical extent of the CEA has been identified by the analysis of existing data to determine the probable maximum extent of future contamination at concentrations above the GWQC. The CEA Proposal includes fate and transport modeling that predicts the future attenuation and migration of contaminants. Based on the analytical data and the fate and transport models used to simulate future conditions, it is predicted that the maximum extent of contamination will never be significantly larger than the current extent of contamination. A period of 5 to 9 years is required for the contaminant concentrations to degrade to less than the GWQC for benzene and CB. The results of the monitoring program at the M-2 Landfill indicate that the groundwater contaminant plume is relatively stable, and has been defined to exist in six distinct areas, covering approximately 50 percent of the Site (see **Figure 10c** of **Appendix H**). In a proactive effort to augment the natural attenuation process, Fort Monmouth is proposing to implement a remedial action for the shallow groundwater at the Site. The following section details the proposed remedial action.

SECTION 4.0
REMEDIAL ACTION WORKPLAN

4.1 CHECK LIST

The RAW was prepared in accordance with the applicable sections of N.J.A.C. 7:26E-6.2 and contains all the applicable requirements listed in that subchapter. Items required for the RAW that have been previously addressed in the remedial investigation sections of this document are referenced or restated as necessary. Specifically, this RAW submittal addresses:

- Remedial Investigations Report pursuant to N.J.A.C. 7:26E-4.8 **(**see **Sections 1, 2, 3 and 4.2)**,

- Soil Remediation Plan **(**see **Section 4.2.4)**
  a) Description of remedial action and remedial technology for each area of concern (N.J.A.C. 7:26E-6.2(a) 5)
  b) Post-remedial sampling (N.J.A.C. 7:26E-6.3 & 6.4)
  c) Compound-specific cleanup goals (N.J.A.C. 7:26E-6.2(a) 4)
  d) Scaled site maps (N.J.A.C. 7:26E-4.9 & 6.2(a) 6)
  e) Permit requirements/applications (N.J.A.C. 7:26E-6.2(a) 8)
  f) System specifications and construction information (N.J.A.C. 7:26E-6.2(a) 9)
  g) Soil erosion and sediment control plan (N.J.A.C. 7:26E-6.2(a) 10)
  h) Soil disposal/soil re-use plan (N.J.A.C. 7:26E-6.4(b)),

- Groundwater Remediation Plan **(**see **Section 4.2.4)**
  a) Plume(s) delineated
  b) Wells properly constructed
  c) Flow direction defined, including groundwater elevation contour maps
  d) Description of remedial action and remedial technology for each area of concern (N.J.A.C. 7:26E-6.2(a) 5)
  e) Compound-specific cleanup goals (N.J.A.C. 7:26E-6.2(a) 4)
  f) Remedial monitoring plan/effectiveness evaluation plan
  g) Hydraulic control information/maintenance
  h) Treated water discharge location
  i) Scaled site maps (N.J.A.C. 7:26E-4.9 & 6.2(a) 6)
  j) Permit requirements/applications (N.J.A.C. 7:26E-6.2(a) 8)
  k) System specifications and construction information (N.J.A.C. 7:26E-6.2(a) 9),

- Data presentation format and quality assurance project plan (N.J.A.C. 7:26E-6.2(a) 7) **–** See **Section 4.2.3.6**,

- Site Specific Health and Safety Plan (N.J.A.C. 7:26E-6.2(a) 11) **–** See **Section 4.2.3.7**,

- Site restoration plan and remedial system dismantling plan (N.J.A.C. 7:26E-6.2(a) 12 &13) - See **Section 4.2.4**,

- Cost estimate (N.J.A.C. 7:26E-6.2(a) 14) - See **Section 4.2.5**, and
- Schedule of implementation (N.J.A.C. 7:26E-6.2(a) 15) **–** See **Section 4.2.3.4**.

4.2 SITE SUMMARY

4.2.1 Summary of Areas of Environmental Concern

As discussed in Section 3, sampling of the surface and subsurface soils, groundwater and surface waters at the M-2 Landfill has delineated the degree and extent of potential contaminants. Benzene and CB are not present in Mill Creek and there are no exceedences of the RDCSCC for these compounds in the soils. The distribution of benzene and CB in the groundwater may be indicative of a combination of biodegradation and retardation (due in part to the low hydraulic conductivity) that limit or prevent migration to Mill Creek. It is reasonable to assume that the concentrations of benzene and CB observed in the shallow groundwater may represent residual, equilibrium concentrations. In regards to remediation, the shallow groundwater is the area of concern that must be addressed. Remedial actions/technologies that accelerate or augment the natural attenuation that appears to be occurring at the landfill will be the objective of this RAW.

4.2.2 Summary of Proposed Remedial Action(s)

4.2.2.1 Area(s) Proposed for Remedial Action

The M-2 Landfill consists of a flat to gently sloping surface cover composed of vegetated soil. This earthen cover is stable, approximately 0 to 2 ft thick, and has been generally undisturbed for more than 30 years. Beneath the earthen cover is fill material consisting of waste mixed with organic material, sand, silt and clay. The fill material ranges in thickness from approximately 4 ft to approximately 10 ft. Beneath the fill is the native soil consisting of silty clays and fine sand. Groundwater is encountered at depths of approximately 8 ft below the surface of the landfill. The groundwater is unconfined (water table conditions) and flows north-northwest towards Mill Creek, which flows eastward into Parkers Creek. Aquifer testing, using monitoring wells installed in the landfill, indicated that the hydraulic conductivity of the saturated materials is low and the groundwater storage capacity of the materials is very low. Consequently, groundwater movement towards Mill Creek is slow.

The area proposed for remedial action at the M-2 Landfill is based upon the findings of the GeoProbe® soil and groundwater investigation conducted in 1999. Figure 13 presents the approximately 185 boring locations where groundwater samples were collected and analyzed for VOC. Figure 13 also presents the detections for benzene and CB and highlights ("outlined in red") the exceedences above the respective New Jersey GWQC. The results of the groundwater investigation establish the areal extent of shallow (0-12 ft bgs) groundwater contamination (defined by several boring locations where benzene and CB were reported below the method detection limits (or Not Detected)). The shallow groundwater contamination can be further

separated into six defined areas as shown on **Figure 13.** The six areas of defined shallow groundwater contamination are proposed for remedial action.

4.2.2.2 Identification of Applicable Remediation/Cleanup Standards

The COC and media for proposed remedial action at the M-2 Landfill are benzene and CB in the shallow groundwater. The applicable remediation/cleanup standards are the respective New Jersey GWQC:

- Benzene – 1 ug/L, and
- Chlorobenzene – 4 ug/L.

4.2.2.3 Proposed Classification Exception Area

As discussed in Subsection 3.3.2 of the RIR, the DPW is proposing the designation of a CEA at the M-2 Landfill site. The Proposal for a CEA at the M-2 Landfill is provided in **Appendix H**. The horizontal and vertical extent of the CEA has been identified by the analysis of existing data to determine the probable maximum extent of future contamination at concentrations above the GWQC. The CEA Proposal includes fate and transport modeling that predicts the future attenuation and migration of contaminants. Based on the analytical data and the fate and transport models used to simulate future conditions, it is predicted that the maximum extent of contamination will never be significantly larger than the current extent of contamination. The CEA Proposal established that a period of 5 to 9 years will be required for the contaminant concentrations to degrade to less than the respective GWQC for benzene and CB and that benzene and CB will not migrate beyond the boundaries of the M-2 Landfill site in the timeframes calculated. The results of the monitoring program at the M-2 Landfill indicate that the groundwater contaminant plume is relatively stable (see **Figure 10c** of **Appendix H**). In a proactive effort to augment the natural attenuation process at the M-2 Landfill, Fort Monmouth is proposing to implement a remedial action for the shallow groundwater.

4.2.2.4 Description of Proposed Remedial Actions/Technologies

The CEA calculated for the M-2 Landfill shows that groundwater contamination for benzene and CB will not migrate from the M-2 Landfill site above the respective GWQC in the timeframes calculated. Therefore, natural attenuation provides a technically defensible argument for "No Further Action" at the M-2 Landfill. However, the DPW prefers to accelerate the natural attenuation processes and has elected to evaluate several technologies to enhance remediation of the shallow groundwater. The proposed remedial actions/technologies to be evaluated at the M-2 Landfill include chemical treatment, bioremediation, and monitored natural attenuation.

Chemical Treatment

In-situ chemical treatment (oxidation) involves the introduction of one or more chemicals (primarily oxidizers such as dissolved oxygen, peroxide, potassium permanganate, or ozone) into

the subsurface, which react with the COC in an exothermic reduction/oxidation (redox) chemical reaction to degrade the contaminants into non-toxic end products (usually carbon dioxide, water and fatty acids). The two primary in-situ chemical treatment (oxidation) methods used within soils and groundwater in the degradation of organic contaminants (such as benzene and CB present at this site) are:

1. dilute hydrogen, magnesium and/or calcium peroxide, also known as oxygen release compounds (ORC); and
2. Fenton reagents, a proprietary blend of iron catalysts, peroxides, and buffers.

In-situ chemical treatment (oxidation) can be undertaken in conjunction with other treatments, such as pump-and-treat, soil vapor extraction and bioremediation, to degrade remaining contaminants. A brief overview of the two in-situ chemical treatment (oxidation) methods is provided below.

Oxygen Release Compounds (ORC)

Oxygen release compounds (ORC) degrades (reduces) to water or hydroxides, therein releasing free oxygen to the system. The free oxygen subsequently is utilized by organisms in the soil/groundwater to break down organic molecules (contaminants) into smaller, simpler, non-toxic substances, such as water and fatty acids. Most ORC blends on the market are too dilute for safety concerns to produce enough free oxygen to create a substantial redox chemical degradation. They serve only as sources of additional oxygen to indigenous microbes in their bioremedial degradation of organic substances (see Bioremediation section below).

Fenton Reagents

The Fenton reagent reaction is a straightforward oxidation process in which larger organic molecules are oxidized or chemically cleaved into simpler, environmental-friendly substances, such as water and carbon dioxide. "Daughter products," or intermediate breakdown products, may be created as the result of the Fenton reagent reaction. However, these daughter products are eventually broken down by the Fenton reagent reaction. The process is extremely rapid, approximately days or weeks, as opposed to bioremediation or natural attenuation, which typically occur over periods of months or years.

The process uses a standard Fenton's reagent procedure that combines hydrogen peroxide and iron (Fe^{+2}). The catalyzed decomposition of hydrogen peroxide to form hydroxyl radicals (OH-), a strong oxidant, occurs as follows:

$$H_2O_2 + Fe^{+2} \rightarrow OH + OH^- + Fe^{+3}$$

The hydroxyl radical (OH-) attacks the carbon-carbon bonds, resulting in cleavage fragments as follows:

$$\text{contaminants} + OH^- \rightarrow \text{daughter products} + H_2O_2 + OH^-$$

Subsequent oxidation results in a breakdown of the contaminant fragments to carbon dioxide and water as follows:

$$\textit{daughter products} + OH^- \rightarrow H_2O + OH + CO_2$$

The Fenton reagent reaction selectively attacks carbon bonds based upon their complexity. Specifically, the presence of the carbon-carbon (C=C) double bonds in the benzene ring of molecules, such as benzene and CB, facilitates the propagation of the hydroxyl radical (OH-) addition reaction followed by ring cleavage to final by-products such as carbon dioxide and water. In short, Fenton reagents are especially reactive with benzene and chlorobenzene-type compounds. Furthermore, they can be used in the oxidation of chlorinated and non-chlorinated hydrocarbons, as well as semi-volatile organic compounds, including pesticides, and polycyclic aromatic hydrocarbons (PAHs).

The volume and chemical composition of individual treatments are based on the contaminant levels and volumes, subsurface characteristics, and pre-application laboratory test results. The methods for delivery of the chemicals may vary. The Fenton reagents are injected through a well or injector head (GeoProbe®) directly into the subsurface or combined with extract (i.e., liquid) from the site and then recirculated.

Bioremediation

Bioremediation is a treatment process that uses naturally occurring microorganisms (yeast, fungi, or bacteria) to breakdown or degrade hazardous substances into less toxic or non-toxic substances. The microorganisms consume and digest organic substances for nutrients and energy. In general, the microorganisms break down the organic contaminants into harmless products – mainly carbon dioxide and water. Once the contaminants are degraded, the microorganism population is reduced (i.e., die) with the declining food source. The dead microorganisms or small populations of microbes in the absence of food pose no contamination risk.

For bioremediation to occur, the microorganisms must be active and healthy. Bioremediation technologies assist microorganisms' growth and increase microbial populations by creating the optimum environmental conditions for detoxification of the maximum mass of contaminants. The specific bioremediation technology used is determined by several factors, including the type of microorganisms present, site conditions, and the quantity and toxicity of the contaminant chemicals. Different microorganisms degrade different types of compounds and survive under different conditions.

Indigenous microorganisms are those microbes that are naturally present at the site. To stimulate the growth of these indigenous microorganisms, the proper soil temperature, moisture content, oxygen, pH, soil redox potential, and nutrient content may need to be provided. An additional carbon source such as molasses or other inexpensive simple carbon chain sugar may be added to promote the rapid growth of the indigenous populations.

If the biological activity needed to degrade a particular contaminant is not present in the soil at the site, microorganisms from other locations, or special commercially available, cultured microbes or enzymes, whose effectiveness has been tested and documented, can be added to the contaminated media. These are called exogenous microbes and enzymes. The conditions at the site must be adjusted to ensure that the exogenous microbes will thrive.

Bioremediation can take place under aerobic and anaerobic conditions. In aerobic conditions, microorganisms use available atmospheric oxygen to function. With sufficient oxygen, and the proper environmental conditions, the microbes will convert many organic contaminants to carbon dioxide and water. Anaerobic conditions support biological activity when no oxygen is present so the microorganisms breakdown chemical compounds in the soil via beta-oxidation to release methane and carbon dioxide. Sometimes, during the aerobic and anaerobic processes of breaking down the original contaminants, intermediate products that are less toxic, equally toxic, or more toxic than the original contaminants are created.

Bioremediation applications fall into two broad categories: in-situ (in-place) or ex-situ (removed, out-of-place). In-situ bioremediation treats the contaminated soil or groundwater where originally detected. Consequently, it may be less expensive, create less dust, and cause less release of contaminants than ex-situ techniques. In addition, it is possible to treat large volume of media at one time using in-situ methods. In-situ techniques, however, are generally slower than ex-situ techniques, but are more cost effective at sites with permeable (i.e., sandy or uncompacted) soil and transmissive aquifers. Ex-situ bioremediation processes require removal of the contaminated soil or groundwater (e.g., excavation of contaminated soil or pumping of groundwater) before treatment. In the case of this Fort Monmouth RAW, only in-situ bioremediation was considered and evaluated.

The goal of aerobic in-situ bioremediation is to supply oxygen and nutrients to microorganisms in the soil. Aerobic in-situ techniques can vary in the way they supply oxygen to the microbes that degrade the contaminants. Two most common methods are bioventing and the injection of hydrogen peroxide. Oxygen can be provided naturally in well-vented soils, by pumping air into the soil above the water table (bioventing) or below the water table (air sparging), or by delivering oxygen in liquid or solid form as hydrogen peroxide or a peroxide salt to the subsurface. In-situ bioremediation may not work well in clays or in highly layered subsurface environments because oxygen cannot be evenly distributed throughout the area. In-situ remediation typically requires years to reach cleanup goals, depending mainly on the biodegradability of the specific contaminant. Less time is generally required with easily degradable contaminants.

Bioventing/Air Sparging Systems

These systems deliver air (oxygen) from the atmosphere into the soil and/or groundwater through injection wells placed in the ground where the contamination exists. The number, location, and depth of the wells depend on many geological factors and engineering considerations.

An air blower may be used to introduce air into the soil/groundwater through the injection wells. Air (oxygen) flowing through the soil/groundwater is used by the microorganisms in the oxidation of the contaminants. Nutrients, soil moisture, pH and soil Redox potential-adjusting chemical agents, and/or commercially available cultured microbes or enzymes, may be applied to the surface or pumped into the injection wells. Nitrogen, phosphorous, and supplemental carbon sources may also be required to increase the growth rate of the microorganisms.

Hydrogen Release Compounds

This method uses hydrogen release compounds (HRC) to enhance in-situ anaerobic bioremediation using proprietary polylactate ester specially formulated for slow release of lactic acid. Bioremediation using HRC is a multi-step process. Indigenous anaerobic microbes metabolize the lactic acid generated by HRC, thereby producing hydrogen. The resulting hydrogen can be used by reductive dehalogenators, which are capable of metabolizing chlorinated hydrocarbons via a process called reductive dechlorination. Major target compounds in this group include the chlorinated aliphatic hydrocarbons, such as PCE, TCE, trichloroethane (TCA), and their derivatives. By providing a long-lasting time-release hydrogen source, HRC enhances anaerobic reductive dechloronation of chlorinated hydrocarbons via anaerobic bioremediation.

Biodegradation is useful for many types of organic wastes, particularly petroleum related compounds (aerobic bioremediation), and chlorinated hydrocarbons (anaerobic bioremediation), and is a cost-effective, natural process. The extent and success of biodegradation is highly dependent on the toxicity and initial concentrations of the contaminants, their respective biodegradability, the properties of the contaminated soil, the particular treatment system, and associated operation of the system to control the soil environment and growth of microorganisms. The effectiveness of bioremediation is limited at sites with high concentrations of metals, highly chlorinated organics, or inorganic salts because these compounds are toxic to microorganisms. In the case of benzene and CB, the primary soil contaminants at the M-2 Landfill, both COC are slow degrading compounds and CB is a halogenated aromatic compound.

The soil must be carefully controlled and monitored to ensure the proper oxygen content, moisture levels, soil nutrients and optional outside carbon source levels, soil pH, soil redox potential, and temperature are maintained to optimize environmental conditions to promote and enhance the growth of microorganisms. Seasonal changes in temperature will also slow or possibly stop the biological process during winter months, as microorganisms are temperature sensitive.

Enzyme-Enhanced Bioremediation (EEB)

The key to any bioremediation process is the control of specific microorganisms under specific environmental conditions to achieve specific chemical transformations. Bioremediation requires this control to be maintained in complex hydrogeological settings to transform often-complex mixtures of compounds to carbon dioxide and water in a process called “mineralization.” The process of transforming a hazardous chemical to a non-hazardous compound in a biological

system is the result of complex biochemical reactions in which microorganisms (bacteria) convert the hazardous compound to energy and cell mass. Bioremediation processes are catalyzed chemical reactions in which the microorganism provides the catalyst (enzyme) to transform a specific compound (contaminant) in an oxygen-reduction (redox) reaction. Enzyme production and the subsequent reaction will not occur unless suitable environmental conditions are carefully maintained. The primary components required to sustain a bioremediation process are: a bacteria species capable of producing "target-specific enzymes" to degrade the contaminant, an energy source (contaminant), and an electron acceptor for the redox reaction. Components of secondary importance are: nutrients, moisture, pH, and temperature. Absence, or even imbalance, of these components may limit the biological process and result in a lack of contaminant transformation. Enzyme Technologies, Inc. (ETEC) of Portland, Oregon, has developed proprietary methods to enhance the bioremediation process. Background information from their Web Site (www.enzymetech.com) has been summarized below to provide an overview of a proposed EEB implementation at the M-2 Landfill.

Oxygenation is extremely important in the performance of an in-situ bioremediation process, often controlling both the overall rate of contaminant degradation as well as the cleanup levels attainable. Maximizing the available oxygen is critical to maximize the degradation rates achievable using the proposed biological enhancement products. There are two common methods for oxygenation of groundwater: 1) air injection; and 2) oxygen (or oxygen-augmented air) injection. With both of these methods, the air or oxygen is forced below the surface into the groundwater to subsequently migrate upward, creating an oxygenated volume of water surrounding the injection location. With air injection, the dissolved oxygen saturation point is approximately 8 to 12 parts per million (ppm), depending on elevation and temperature. With pure oxygen injection, the dissolved oxygen can typically be increased to 15 to 20 ppm. ETEC manufactures a "BioBox®" for use at sites that incorporates a unique oxygen mixing process to achieve dissolved oxygen concentrations in the water of 40 ppm or greater, achieving full solubility of the oxygen into the water. This is a highly beneficial condition for the purposes of achieving contaminant degradation.

The proposed biological enhancements at the M-2 Landfill would consist of four different products: Enzyme Accelerator (EA), Multi-Enzyme Complexes (MZC), TPH Bacterial Consortium (A2), and Custom Blend Nutrients (CBN). A description of each of the proposed enhancements is provided below:

- EA acts as a pre-treatment agent for enzyme and bacterial applications. EA is a liquid biosurfactant that increases the surface area for enzymes and bacteria, thereby increasing the cleanup rate.
- MZC is a concentrated liquid extract of mono- and dehydroxygenase compounds that are responsible for over 90% of the bioremediation process.
- A2 is a liquid multi-strain bacterial consortium specifically designed to degrade long-chain petroleum hydrocarbons.
- CBN is dry mixture of proprietary nitrogen, phosphorus, and potassium compounds with micronutrients.

The application of biological enhancements are typically accomplished by using a Geoprobe® rig to install an array of temporary injection points for introduction of the biological enhancements. Injection of the biological products would be continuous from ground surface to the selected depth and would be performed in two stages. During stage one, the EA and MZC are mixed in the BioBox® and injected into the ground. During stage two, the CBN and A2 are mixed in the BioBox® and then injected into the same locations. Performance monitoring of the area is then conducted for operational parameters (e.g., dissolved oxygen) followed by confirmatory sampling and analysis at the completion of the treatment period.

Monitored Natural Attenuation

The term "monitored natural attenuation" refers to the reliance on the *natural attenuation process* (within the context of a carefully controlled and monitored site cleanup approach) to achieve site-specific remediation objectives within a period that is "reasonable" compared to that offered by other more active methods.

The term "monitored natural attenuation" became EPA policy under OSWER Directive (9200.4-17P) with the objective to emphasize and require that a long-term monitoring program become an important component of a remedy where natural processes are to be relied upon to achieve the cleanup objectives. The intent of the directive was to distinguish between the case where "monitored natural attenuation"(MNA) is used as a remedy, as opposed to the case where "natural attenuation" processes are occurring as part of a no-action remedy and are not being relied upon to attain a remedial objective. The NJDEP has also accepted "monitored natural attenuation" as an optional remedy for the cleanup of a contaminated site, particularly in the case of underground storage tanks.

"Natural attenuation" is the effect of natural processes (i.e., those which do not require human intervention such as engineered enhancement or controls) which reduce the mass, toxicity, mobility, volume, or concentration of contaminants in soil or groundwater. It is a passive method of treatment; however, EPA and NJDEP expect that source control and long-term performance monitoring will be fundamental components of any remedy that relies primarily on natural attenuation processes. EPA and NJDEP do not view MNA to be a "no action" or "walk-away" approach, but rather consider it to be an alternative means of achieving remediation objectives that may be appropriate for specific, well-documented site circumstances where it meets the applicable statutory and regulatory requirements.

In the majority of cases where MNA is proposed as a remedy, its use may be appropriate as one component of the total remedy, that is either in conjunction with active remediation or as a follow-up measure. In general, MNA should be used cautiously as the sole remedy at contaminated sites.

The "natural attenuation processes" that are in operation in such a remediation approach include a variety of physical, chemical, or biological processes that, under favorable conditions, act without human intervention to reduce the mass, toxicity, mobility, volume, or concentration of contaminants in soil or groundwater. These in situ processes encompass biodegradation;

dispersion; dilution; sorption; volatilization; radioactive decay; and chemical or biological stabilization, transformation, or destruction of contaminants.

MNA is appropriate as a remedial approach where it can be demonstrated as being capable of achieving a site's remediation objectives within a timeframe that is considered "reasonable" compared to that offered by other methods, and where it meets applicable remedy selection criteria. Therefore, sites where the contaminant plumes are no longer increasing in extent, or are shrinking, would be the most appropriate candidates.

The timeframe required for MNA remedies is often longer than that required for remedies that are more active. Consequently, the uncertainty associated with the natural attenuation processes increases dramatically, as well as the ability to establish the performance monitoring standards capable of verifying the performance expected from natural attenuation in a timely manner (e.g., five to ten year monitoring period).

Potential advantages of using MNA include:

- As with any in situ process, generation of lesser volume of remediation wastes, reduced potential for cross-media transfer of contaminants commonly associated with ex-situ treatment, and reduced risk of human exposure to contaminants, contaminated media, and other hazards, and reduced disturbances to ecological receptors;
- Some natural attenuation processes may result in in-situ destruction of contaminants;
- Less intrusion as few surface structures are required;
- Potential for application to all or part of a given site, depending on site conditions and remediation objectives; and
- Potentially lower overall remediation costs than those associated with active remediation.

The potential disadvantages of using MNA include:

- Longer time frames may be required to achieve remediation objectives, compared to active remediation measures at a given site;
- Site characterization is expected to be more complex and costly;
- Toxicity and/or mobility of transformation products may exceed that of the parent compound;
- Long-term performance monitoring will generally be more extensive and for a longer time frame;
- Institutional controls may be necessary to ensure long term protectiveness;
- Potential exists for continued contamination migration, and/or cross-media transfer of contaminants; and
- Hydrologic and geo-chemical conditions amenable to natural attenuation may change over time and could result in renewed mobility of previously stabilized contaminants (or naturally occurring metals), adversely influencing the remedial effectiveness.

The attenuation factor of organic chemical compounds has been empirically calculated as a function of its organic partitioning coefficient (KOC) and its half-life in the environment. The

half-lives of organic substances is reported in the *Handbook of Environmental Degradation Rates,* authored by Howard, Boethling, Jaris, Meylan, and Michalenko. The empirical calculation is

Attenuation Factor (AF) = K x KOC

Where: **K = degradation coefficient = 0.693/ $T_{1/2}$**

$T_{1/2}$ = half life of the organic compound

The half-lives of the compounds of concern in the shallow groundwater at the M-2 Landfill (benzene and CB) are as high as 24 months and 300 days, respectively. The KOC for each compound is 58 and 200, respectively. This equates to an AF of 0.35 and 0.58, respectively.

The half-life of benzene is relatively large, i.e., approximately two years. It is relatively resistant to degradation in the environment without active enhancement. Similarly, the half-life of CB is almost one year. Their persistence in the environment is greater than that of more biodegradable compounds or other related petroleum compounds. Use of the MNA process at the site would probably take up to ten years. Therefore, it is recommended that a more active remedy be implemented to reduce the timeframe of the remedial solution.

4.2.3 Proposed Remedial Alternative

The proposed remedial alternative for the M-2 Landfill includes:

- Maintaining the current institutional controls to limit direct contact with the site, and
- Continued groundwater and surface water monitoring to demonstrate that contaminant degradation due to natural attenuation is a constant and ongoing process.

In addition, the DPW proposes to implement EEB to enhance the natural attenuation occurring at the landfill and more directly impact the shallow groundwater. EEB will be applied within six defined areas where elevated levels of benzene and/or CB were detected during the March 1999 landfill investigation. **Figure 13** shows the six areas proposed for remedial action. Approximately eight (8) boring locations within each of the six delineated areas having had shallow groundwater detections of benzene and/or CB above the respective NJDEP GWQC will be selected for application of the biological enhancements. The initial boring locations were surveyed using GPS; this will allow the injections to be performed directly adjacent to the March 1999 sampling locations.

ETEC will support the proposed remedial action at the M-2 Landfill by providing the four (4) biological enhancements (EA, MZC, A2, and CBN) and the mixing equipment (i.e., Biobox®). The application of biological enhancements will be accomplished using a Geoprobe® rig to install an array of nine (9) temporary injection points around each selected boring location for introduction of the biological enhancements. The injection points will be established on 5-foot

centers for a total of 432 injection locations. Injection of the biological products will be continuous from 4 ft to 8 ft bgs.

The biological enhancements will be injected in two stages. During stage one, the EA and MZC will be mixed in the BioBox® and injected into the ground. During stage two, the CBN and A2 will be mixed in the BioBox® and then injected into the same locations. A maximum production rate of twenty (20) injection points per day has been estimated. Based on this rate, the 1st stage of biological enhancements will be injected at two (2) boring locations during one day (9 injections per location) followed by the 2nd stage the next day.

The injection procedure will be conducted as follows:

- Based on the established grid system from the March 1999 landfill investigation, the selected boring locations and the planned injection grid will be marked on the ground.
- Required contacts for utility clearances will be made and performed. This information will be confirmed in the daily site logs.
- The Geoprobe® rig will be positioned at the proposed injection location and advanced to the initial application depth (8 ft bgs).
- Once the probe is inserted to the initial application depth, the BioBox® injection hose will be connected to the Geoprobe® assembly using an adapted union.
- After both stages of enhancement injection have occurred, each Geoprobe® borehole will be properly abandoned.

During performance of the injection program, an observation of increasing injection pressures and decreasing flow rates should indicate an impermeable boundary. Should this situation be observed, a decision will be made regarding relocation of the proposed injection point.

In addition, approximately 30 days after the completion of the 2-stage injection process, ORC will be applied to the same treatment area again using a Geoprobe® to supplement the free oxygen concentration. Bioremediation will then be allowed to continue for a 12-month treatment period. Long-term groundwater monitoring at the landfill and surface water monitoring at Mill Creek will be continued. The long-term groundwater-monitoring program will be modified as follows: MW01, MW-04, MW-17, and MW-22 will be properly closed and eliminated from sampling. Samples from the remaining 20 groundwater monitoring wells will be as follows: TCL VOC (+15) during three of the four quarters and the 4th Quarter will include TCL VOC (+15), TCL BNA (+15), pesticides, PCB, and TAL metals. The full TCL and TAL analyses will be performed on samples collected in the fall months of the year, which is the Quarter most likely to contain exceedences of the GWQC standards. This is often due to decreased levels of precipitation and, therefore, groundwater dilution.

The current institutional controls in place at the M-2 Landfill (i.e., the site is located on an Army-controlled installation and is surrounded on three sides with a six-foot high chain link fence and on the fourth side by Mill Creek) will be maintained. Periodic inspections of the fencing and landfill cover will be continued.

To address the PCB concentrations detected in soil at the M-2 Landfill, the DPW will incorporate a document equivalent to a DER into the Fort Monmouth Installation Master Plan for soils containing PCB to restrict site development and future use of the M-2 Landfill site, and recognize the planned long-term monitoring of this area. The DPW is the lead agency for all land use issues at Fort Monmouth. The Installation Master Plan resides in the Engineering Services and Planning Division of the DPW. A formal DER cannot be established since Fort Monmouth is a Federal facility and as such, no deed exists.

4.2.3.1 Required Permits and Approvals

Requested Authorization for Discharge to Ground Water by Permit-By-Rule

As provided in N.J.A.C. 7:14A-7.5 (Authorization of Discharges to Ground Water By Permit-By-Rule), Subsection (b), any person responsible for discharges to groundwater listed in 3i through v are deemed to have a permit-by-rule if the discharge occurs when: 1) NJDEP is remediating a contaminated site as defined in N.J.A.C. 7:26C-1.3, pursuant to the rules at N.J.A.C. 7:14B implementing the Underground Storage of Hazardous Substances Act (N.J.S.A 13:1K-6 *et seq.*), or when the owner or operator of a contaminated site is conducting remediation under NJDEP oversight, or the requirements of the Spill Compensation and Control Act (N.J.S.A. 58:10-23.11), or the Procedures for Department Oversight of the Remediation of Contaminated Sites at N.J.A.C. 7:26C; and 2) the person is in receipt of written approval from NJDEP.

The groundwater discharges authorized by permit-by-rule, N.J.A.C. 7:14A-7.5, under Subsection (b) include:

(iv). Discharges to groundwater not to exceed 180 calendar days from any other facility or equipment associated with monitoring, engineering, remedial activities, or design studies necessary to evaluate a contaminated site.

By submittal of this RAW, Fort Monmouth is requesting written approval for Permit-by-Rule for the proposed EEB and ORC application and discharge to groundwater.

Requested Approval for Disruption of Landfill

N.J.A.C. 7:26-2A(j) states that written approval for disruptions of landfills are to be obtained from the NJDEP prior to any excavation, disruption, relocation or removal of any deposited material, which may or may not involve solid waste, from either an active, terminated, or closed sanitary landfill. "Minor" disruptions of a landfill include (but are not limited to): the performance of soil borings and test pits, methane gas surveys, and installation of piezometers and observation wells. The planned injection of biological enhancements and ORC at the M-2 Landfill utilizing a Geoprobe® could be presumed to be a minor disruption of a landfill. However, as provided in N.J.A.C. 7:26-2A.8(j)(iii), a separate disruption approval is not required when the landfill owner has submitted documentation and received prior approval from the NJDEP in the form of several specific instances including "approval for specific construction activities".

By submittal of this RAW, Fort Monmouth is requesting approval for the proposed remedial action at the M-2 Landfill and, more specifically, the injection of biological enhancements and ORC and, therefore, should be exempted from the requirement to submit a Sanitary Landfill Disruption Application.

4.2.3.2 Deed Notification

Fort Monmouth is a Federal facility and as such, no deed exists. To address the PCB concentrations detected in soil at the M-2 Landfill, the DPW will incorporate a document equivalent to a DER into the Fort Monmouth Installation Master Plan for soils containing PCB to restrict site development and future use of the M-2 Landfill site, and recognize the planned long-term monitoring of this area. The DPW is the lead agency for all land use issues at Fort Monmouth.
The Installation Master Plan resides in the Engineering Services and Planning Division of the DPW. A formal DER cannot be established since a deed for Fort Monmouth does not exist.

4.2.3.3 Location of Proposed Remedial Treatment Units

The planned EEB implementation and follow-up ORC application will be performed utilizing mobile/trailer mounted equipment and a GeoProbe® to bore directly through the ground surface in a grid pattern established across the landfill. There are no structures or facilities that require placement onsite, dismantling, or site restoration.

4.2.3.4 Implementation Schedule

The DPW has awarded a contract for performance of the planned remedial action presented within this RAW. Following approval of this RIR/RAW by the NJDEP, the implementation schedule will be as follows:

- Preparation of required plans (e.g., Site-specific Health and Safety Plan) – 14 days.
- Procurement and delivery to the site of the BioBox® and biological enhancement products – 30 days.
- Site mobilization/clearances and utility connection – 5 days.
- Establish and survey injection grid – 3 days.
- Performance of 2-stage EEB injection – 60 days.
- Demobilization – 2 days.
- Initial treatment period – 30 days.
- Injection of ORC – 30 days.
- Performance monitoring of the enhanced bioremediation - 12 months.
- Confirmatory sampling and analysis – 21 days.
- Remedial Action Report – 8 weeks following receipt of analytical data from confirmatory sampling.

Progress reports will be prepared and submitted quarterly to the NJDEP for the duration of the proposed remedial action.

4.2.3.5 Soil and Sediment Erosion

As described within this document, the proposed remedial measures will be accomplished using a GeoProbe®. There is no planned disturbance of the soil within the landfill as part of the proposed remedial measures. Soil and sediment erosion control measures will be implemented to minimize the transport of soil onto the installation roadways (e.g., placement of straw, gravel at the entrance gate of the landfill) from vehicles entering and exiting the site.

4.2.3.6 Quality Assurance Project Plan

Field sampling activities will be conducted in accordance with the NJDEP Field Sampling Manual. Fort Monmouth Environmental Testing Laboratory (NJDEP Certification #13461) will conduct all analyses in accordance with the New Jersey Laboratory Certification Program. A separate Quality Assurance Project Plan will not be submitted for the planned EEB implementation.

4.2.3.7 Site Specific Health and Safety Plan

As required under N.J.A.C.7:26E-1.9, a site-specific health and safety plan (SHSP) will be prepared for the proposed remediation activities. The SHSP will be prepared in accordance with the most recently adopted and applicable general industry (29 CFR 1910) and construction (29 CFR 1926) standards of the Federal Occupational Safety and Health Administration (OSHA), U.S. Department of Labor, as well as any other Federal, State, or local applicable statutes or regulations. All personnel involved in the remediation activities will adhere to the SHSP.

4.2.4 Site Restoration Plan and Remedial System Dismantling Plan

The planned EEB implementation will be performed utilizing mobile/trailer-mounted equipment and a GeoProbe® to bore directly through the ground surface. There are no structures or facilities that will require site restoration or dismantling.

4.2.4.1 Post-remedial Sampling and Monitoring

Following completion of the 12-month treatment period, confirmatory sampling will be undertaken within the six delineated zones and analyzed for VOC. The post-injection groundwater sampling will be performed directly adjacent to selected Geoprobe® boring locations from the March 1999 landfill investigation that had detections of benzene and/or CB above the respective NJDEP GWQC. The initial boring locations were surveyed using GPS; this will allow the post-injection sampling to be performed directly adjacent to the initial sampling locations. The samples will be collected at the groundwater interface to evaluate the direct impact of EEB (the primary focus of this effort). Approximately ten samples will be collected

within each of the six zones for a total of 60 confirmatory samples. The samples will be collected using standard Fort Monmouth DPW Geoprobe® sampling procedures and analyzed for VOCs + 10 (EPA SW-846 Method 8260). In addition, quarterly groundwater monitoring at the landfill and surface water monitoring along Mill Creek will be continued.

4.2.5 Remedial Action Costs

The estimated order of magnitude costs for implementation of the proposed EEB at the M-2 Landfill are provided below. The primary assumptions utilized in estimating the order of magnitude costs are as follows:

- Enzyme injection will be performed utilizing a truck-mounted GeoProbe® and mixing tank (BioBox®). There are no proposed capital costs associated with the planned remedial action. The treatment system will be removed from the site following completion of the injection program.
- All work will be performed in Level D Personnel Safety Protection. No site-specific air monitoring will be performed.
- The injection program will specifically target six areas using eight boring locations within each area, totaling 48 injection locations. A Geoprobe® rig will be used to install an array of nine temporary injection points around each selected boring location, totaling 432 injection points. The injection of the biological products will be continuous between depths of 4-8 ft bgs.
- Approximately 432 injection points will be installed utilizing a 2-stage injection of the biological enhancements. A production rate of twenty (20) injection points per day has been estimated. Based on this rate, the first stage of biological enhancements will be injected at two boring locations during one day (9 injections per location) followed by the second stage the following day.
- Periodic sampling will be performed for nutrients and dissolved oxygen and for VOC in soils.
- There are no proposed capital costs associated with the planned remedial action.
- Confirmatory groundwater samples will be analyzed for VOC in accordance with the NJ Laboratory Certification Program by the Fort Monmouth Environmental Testing Laboratory (NJDEP Certification #13461).

Estimated Order of Magnitude Costs
Proposed Enzyme-Enhanced Bioremediation

TASK	**ESTIMATED COSTS**
1. Plan Preparation	$ 4,200
2. Site Mobilization	$ 8,200
3. GeoProbe® Injection	$ 45,300
4. Enzyme-Enhanced Bioremediation System	$ 75,200
5. ORC application	$ 42,960 (1)

6. Demobilization	$ 1,450
7. Performance sampling during the treatment period and confirmatory sampling	$ 21,550 (2)
TOTAL ESTIMATED COSTS	$198,860

NOTES: (1) Materials cost only, does not include costs for manpower and equipment.
(2) Excludes continued performance of Fort Monmouth groundwater and surface water monitoring program.

4.2.6 Maintenance and Evaluation Schedule for Engineering and Institutional Controls

Institutional controls are in place at the M-2 Landfill (i.e., the site is located on an Army controlled installation and is surrounded on three sides with a six-foot high chain link fence and on the fourth side by Mill Creek to the north). Following completion of the proposed remedial action, the existing institutional controls will be maintained and periodic inspections performed.

4.3 PROGRESS REPORTS

As required by N.J.A.C. 7:26E-6.5(b), Remedial Action Progress (RAP) Reports will be prepared and submitted Quarterly. The RAP Reports will include the following information:

- Summary of the remedial actions accomplished during the reporting period;
- Deviations from and/or proposed modifications to the approved RAW;
- Reporting of problems/delays in the implementation of the RAW, as well as proposed corrective actions with, as applicable/appropriate, changes to the approved project schedule;
- A revised project schedule, including the status of all permit applications;
- Identification of planned remedial actions for the next reporting period;
- A listing of all types and quantities of waste generated by the remedial action during the reporting period and to date, including the name(s) of disposal facilities, and transporters' dates of disposal, and if appropriate, the manifest numbers of each waste load; and
- Supporting documentation (e.g., photographs).

In addition, on an annual basis the actual costs of remediation that have been incurred to date will be summarized and presented.

Only detected compounds are listed.
All concentrations are given in milligrams per kilogram (mg/Kg), equivalent to parts per million (ppm).
* Regulatory levels are based on NJDEP's Residential Direct Contact Soil Cleanup Criteria (RDCSCC).
Exceedances of the RDCSCC are highlighted and printed in **bold-faced** type.

NOTES

Only detected compounds are listed.

All concentrations are given in micrograms per liter (ug/L), equivalent to parts per billion (ppb).

* Regulatory level shown is higher of PQL and Ground Water Quality Criteria as per NJAC 7;9-6

Exceedances of the NJDEP GWQC are highlighted and printed in **bold-faced** type.

D = Results are from a Dilution of the Sample

J = compound Identified Below Detection Limit

ND: Not Detected

NLE: No regulatory limit has been established for this parameter.

PQL: Practical Quantitation Limit

NOTES

Only detected compounds are listed.

All concentrations are given in micrograms per liter (ug/L), equivalent to parts per billion (ppb).

* Regulatory level shown is higher of PQL and Ground Water Quality Criteria as per NJAC 7;9-6

Exceedances of the NJDEP GWQC are highlighted and printed in **bold-faced** type.

D = Results are from a Dilution of the Sample

J = compound Identified Below Detection Limit

ND: Not Detected

NLE: No regulatory limit has been established for this parameter.

PQL: Practical Quantitation Limit

NOTES
All concentrations are given in micrograms per liter (ug/L), equivalent to parts per billion (ppb).
Exceedances of the NJDEP Groundwater Quality Criteria (GWQC) are highlighted and printed in bold-faced type.
ND: Analyte not detected in sample.
NLE: No GWQC exists for this analyte.

Zinc	83.5	392	100	33.6	51.7	47.0	11.3	5000

NOTES
All concentrations are given in micrograms per liter (ug/L), equivalent to parts per billion (ppb).
Exceedances of the NJDEP Groundwater Quality Criteria (GWQC) are highlighted and printed in bold-faced type.
ND: Analyte not detected in sample.
NLE: No GWQC exists for this analyte.

the Fort Monmouth DPW.

APPENDIX A

FORT MONMOUTH
STANDARD OPERATING PROCEDURES

STANDARD OPERATING PROCEDURE

SOP No.: SAM-0210
Revision No.: New
Date Revised: 3-24-99

CATEGORY: Sample Handling
TITLE: Geoprobe Sampling Methods for Site M-2 Benzene Investigation

1 PURPOSE: To document the procedures used for sample collection.

2 RESPONSIBILITY: Designated field samplers who have been properly instructed and trained in field sampling protocol and techniques.

3 REFERENCES:

3.1 Field Sampling Procedures Manual, May 1992. New Jersey Department of Environmental Protection.

3.2 Geoprobe Tools and Equipment Catalog 98/99.

4 SUMMARY: This SOP represents all general field sampling requirements as required by the NJDEP. It specifically addresses the proper use of protective equipment, collection of QA/QC samples, field decontamination procedures, proper documentation of all field activities, collection of samples into proper containers with the proper preservation and the techniques for collecting each type of sample.

4.1 As a minimum, all field personnel are required to have work boots (steel toe construction), safety glasses or goggles, hard hat and gloves available for all sampling activities. Standard latex surgical gloves are worn at all times when samples were collected or handled.

4.2 Proper documentation of all site activities is crucial. Documentation is maintained to trace the possession and handling of samples from the time of collection, through analysis and disposal.

4.3 Every field sampler (team) is required to maintain a bound field-sampling logbook with permanently numbered pages. All field activities and notes are documented in this book. Notations are made in logbook fashion, noting the time and date of all

Prepared By _____ Date 3-24-99

Approved By _____ Date 3-24-99
QA Manager / Laboratory Director

entries. Information recorded in the logbook includes name and location of site investigation, date and time of arrival and departure, persons contacted, weather conditions, samples taken, method and time of collection and depths if required. Field instrument calibrations are kept in separate books.

4.4 Sample containers are labeled after sample collection. Sample labels include the following: well or sample number, parameters, preservatives, date and time of sample collection, sampler's initials and site name/location.

4.5 The sample containers utilized during the execution of this project are as follows:

4.5.1 (1) Two ounce clear glass containers with Teflon lined lids.
4.5.2 (1) Two ounce clear glass containers with septum.
4.5.3 (2) 40ml clear VOA vials.

4.6 A chain of custody (COC) form is completed in the field and accompanied each set of samples collected. The COC is a legal record of possession of the samples and of request for analysis. It bears the name of the person assuming responsibility of the sample. A copy of a COC can be found in SAM-0201 Attachment 2 (Sample Receiving, Log-In and Disposal).

4.7 Sample collection techniques are accomplished as follows:

4.7.1 The Macro Core Sampler ® is utilized in the extraction of the soil samples (Ref.5.1). The soils are taken using the methanol extraction method (Ref. SAM 0207).
4.7.2 After completion of the soil samples, a pre-probe is driven approximately three feet into the saturated water zone and extracted (Ref.6.2).
4.7.3 A one-inch polyvinyl chloride (PVC) screen is carefully placed in the bore-hole into the saturated zone (Ref.6.2).
4.7.4 A peristaltic pump is then used to purge the ground water from the PVC screen (Ref.6.3).
4.7.5 A sample is taken using a disposable polyethylene bailer.

4.8 Samples are properly preserved and the correct size, shape and color containers are used. Guidelines for sample containers and preservation can be found in SOP SAM-0200 (Sample Containers, Preservation and Holding Time).

4.9 Equipment List:

4.9.1 Geoprobe Macrocore Sampler® Assembly
4.9.2 Bedrock one inch .10 slot, schedule 40, PVC screen
4.9.3 Bedrock one inch schedule 80 PVC point
4.9.4 Bedrock one inch schedule 40 PVC riser
4.9.5 3/8" food grade polyethylene tubing (disposable)
4.9.6 ¼" I.D. surgical tubing
4.9.7 Masterflex® Peristaltic Pump

4.10 Decontamination Procedures for Field Sampling Equipment

4.10.1 Items de-contaminated are as follows:

4.10.1.1 Macro Core Sampler® and associated parts.
4.10.1.2 Pre-probe point and rods implemented in its use.

4.10.2 Aqueous Sampling Decontamination Steps:

4.10.2.1 Detergent plus tap water wash
4.10.2.2 Generous tap water rinse
4.10.2.3 DI water rinse
4.10.2.4 acid rinse (if sampling for metals)
4.10.2.5 DI water rinse
4.10.2.6 Acetone rinse (if sampling for organic parameters)
4.10.2.7 Total air dry
4.10.2.8 DI water rinse

4.10.3 Non-Aqueous Sampling Decontamination Steps:

4.10.3.1 Detergent plus tap water wash
4.10.3.2 Generous tap water rinse
4.10.3.3 DI water rinse

5 GEOPROBE SAMPLING FOR SOILS:

5.1 Sampling with the Macro Core Sampler: The Macro Core sampler is a steel tube that measures two inches in diameter by forty-eight inches in length. The complete assembly consists of the tube, a cutter shoe, a liner tube, and a drive head that is connected to drill rod and advanced into the soil strata. The liner is manufactured of Polyethylene Tera-Phthalate Glycol (PETG) material as well as other materials. The liner is one point seventy-five inches diameter and forty-six inches long. It can hold up to approximately thirteen hundred milliliters of soil when full recovery is obtained. The sampler is decontaminated (Ref.4.10.3), put together and introduced into the soil from zero grade and driven to the desired depth. The sampler is meant to be used mainly as an open advanced borehole system. The sampler is pushed and or percussion hammered into the soil, extracted out of the soil, and opened up.

5.2 Sampling Procedures: After the sampler is extracted out of the bore-hole, the liner is removed, cut open and screened with a photo ionization instrument (HNU®) and/or a flame ionization instrument (OVA®). Samples recovered from the vadose zone for VOA analysis are collected using the methanol extraction method (REF. SAM 207). Samples are taken when instrument (high fid/pid) and or visual observations were made (oily sheen). If there is no presence of any of the above factors, a sample will be taken at the vadose zone only. These samples are collected as soon as possible to prevent contaminant volatilization. Additional VOA samples will also be collected from other intervals of the soil column based upon visual observations and field instrument readings. In the absence of such readings, no additional samples will be taken. Field notes are written as to note soil structures, colors and any other materials. Odors and any other factors regarding the sample are noted as well.

6 GEOPROBE SAMPLING FOR GROUNDWATER:

6.1 Ground Water Sampling with the use of a Passively Placed Narrow Diameter Point (PPNDP): A narrow diameter point (PPNDP) is a small diameter («-1 inch OD) screened casing passively placed in a bore-hole. A solid push rod (pre-probe) is used to create a narrow diameter hole to a depth below the water table. This is performed with a rotary hammer. A piece of schedule 40 PVC screen with 0.010-inch slots and an end cap are placed at the bottom of each bore-hole from the point where the last soil sample is collected. No filter or gravel pack is used in the construction of each well sampling point. Each well point is utilized for a period of less than 48 hours.

6.2 Installation: Within each bore-hole, commencing from the point where the last soil sample is collected, the pre-probe is driven to a depth of 1-3 feet below the water table. The screened section of PVC is placed into the borehole so the screened interval is across the ground water table. Prior to installation of the PPNDP, knowledge of the depth to water is established from previous soil sampling activities.

6.3 Sampling Procedure: Three to five volumes of the standing water in the PPNDP is purged prior to sample collection. This is accomplished utilizing a peristaltic pump. The tubing used for the well purging is food grade polyethylene and silicon surgical tubing that is discarded after each purging event. Disposable polyethylene bailers are used to collect ground water samples for VOA analysis. Following sample collection, the PVC screen is removed from each borehole. Granular bentonite is then added to a level just above the saturated zone. Soils previously removed during sampling activities are then reintroduced back into each borehole and compacted.

6.4 Quality Assurance/Quality Control: The PPNDP and associated equipment (bull point, riser pipe, etc.) are decontaminated between borings using the following procedure: 1) Remove all adherent soil material. 2) Wash with a laboratory grade glassware detergent. 3) Rinse with potable water. 4)Rinse with distilled and de-ionized ASTM Type II water. Field blanks are obtained in the same manner as the sample. The blank water is passed through the sample device and the PPNDP prior to installation, then into the sample container. The parameters and frequency for field blanks are designated in the May 1992 edition of the NJDEP Field Sampling Procedures Manual.

7 QUALITY CONTROL:

7.1 QA/QC samples are intended to provide control over the collection of environmental measurements and subsequent validation, review and interpretation of generated analytical data.

7.1.1 The trip blanks are used exclusively for volatile organic analysis, (aqueous sampling only) and its purpose is to measure possible cross contamination of samples during shipment to and from the site. The trip blanks are never opened and travels to the site with the empty sample bottles and back from the site with the collected samples. Contaminated trip blanks may indicate bottle cleaning or blank water of questionable quality. Trip blanks are included at the rate of one per day.

7.1.2 The purpose of a field blank is to place a mechanism of control on sample equipment handling, preparation, storage and shipment. Field blanks travel and are stored with the sample bottles. Field blanks are collected in the following manner. Two identical sets of bottles are prepared. One set is filled with laboratory demonstrated analyte free water (same water used for trip and method blanks). All of the filled bottles are shipped with the other empty sample containers. At the field location, in an area where contamination is suspected, the water is passed from the full set of like-bottles through the dedicated or field decontaminated sampling device and into the empty set of like-bottles. Field blanks are preserved identically to samples receiving the same analyses. Field blanks are collected and analyzed for all of the same parameters as the samples collected that day.

7.1.3 Duplicate sample collection. For aqueous samples, duplicates are taken by alternating filling containers from the same sampling device for each of the required parameters. VOA samples, to include duplicate samples, are always taken from discrete locations or intervals without compositing or mixing. Duplicates are collected at the rate of one per twenty.

STANDARD OPERATING PROCEDURE

SOP No.: SAM-0208
Revision No.: New
Date 3-24-99

CATEGORY: Sample Handling
TITLE: Geoprobe Sampling Methods for Site M-2 PCB

1 PURPOSE: To document the procedure used to collect samples to delineate PCB contamination around Monitor Wells 6 and 9 at the M-2 landfill.

2 RESPONSIBILITY: Designated field samplers who have been properly instructed and trained in field sampling protocol and techniques.

3 REFERENCES:

3.1 Field Sampling Procedures Manual, May 1992. New Jersey Department of Environmental Protection.

3.2 Geoprobe Tools and Equipment Catalog 98/99.

4 SUMMARY: This SOP represents all general field sampling requirements as required by the NJDEP. It specifically addresses the proper use of protective equipment, collection of QA/QC samples, field decontamination procedures, proper documentation of all field activities, collection of samples into proper containers with the proper preservation and the techniques for collecting each type of sample.

4.1 At a minimum, all field personnel are required to don work boots (steel toe construction), safety glasses or goggles, hard hat and gloves available for all sampling activities. Standard latex surgical gloves are worn at all times when samples are collected or handled.

4.2 Proper documentation of all site activities is crucial. Documentation is maintained to trace the possession and handling of samples from the time of collection, through analysis and disposal.

Prepared By _____ Date 3-24-99

Approved By _____ Date 3-24-99
QA Manager / Laboratory Director

4.3 Every field sampler (team) is required to maintain a bound field-sampling logbook with permanently numbered pages. All field activities and notes are documented in this book. Notations are made in logbook fashion, noting the time and date of all entries. Information recorded in the logbook includes name and location of site investigation, date and time of arrival and departure, persons contacted, weather conditions, samples taken, method and time of collection and depths if required. Field instrument calibrations are kept in separate books.

4.4 Sample containers are labeled after sample collection. Sample labels included the following: well or sample number, parameters, preservatives, date and time of sample collection, sampler's initials and site name/location.

4.5 The sample container types to be utilized during the execution of this project are as follows:
4.5.1 (1) Four-ounce clear glass containers with Teflon lined lid.
4.5.2 (1) 1000 ml Boston Round Amber glass container with Teflon lined lid.

4.6 A chain of custody (COC) form is completed in the field and accompanied each set of samples collected. The COC is a legal record of possession of the samples and of request for analysis. It bears the name of the person assuming responsibility of the sample. A copy of a COC can be found in SAM-0201, Attachment 2 (Sample Receiving, Log-In and Disposal).

4.7 Sample techniques are accomplished as follows:

4.7.1 The Macro Core Sampler ® will be utilized in the extraction of the soil samples (Ref.5.1). The soils are placed in the appropriate container, sealed, labeled and placed in a cooler containing ice.

4.7.2 After completion of the soil sampling activities, a pre-probe is driven approximately three feet into the saturated water zone and extracted (Ref.6.2).

4.7.3 A one-inch polyvinyl chloride (PVC) screen is carefully placed in the borehole into the saturated zone (Ref.6.2).

4.7.4 A peristaltic pump is used to purge the groundwater from the PVC screen (Ref.6.3).

4.7.5 A sample is then taken directly from the purge tube line.

4.8 Samples are properly preserved and the correct size, shape and color containers are used. Guidelines for sample containers and preservation can be found in SOP SAM-0200 (Sample Containers, Preservation and Holding Time).

4.9 Equipment List:
- 4.9.1 Geoprobe Macrocore Sampler® Assembly
- 4.9.2 Bedrock one inch .10 slot, schedule 40, PVC screen
- 4.9.3 Bedrock one inch schedule 80 PVC point
- 4.9.4 Bedrock one inch schedule 40 PVC riser
- 4.9.5 3/8" food grade polyethylene tubing (disposable)
- 4.9.6 ¼" I.D. surgical tubing
- 4.9.7 Masterflex® Peristaltic Pump

4.10 Decontamination Procedures for Field Sampling Equipment:

4.10.1 Items de-contaminated are as follows:
- 4.10.1.1 Macro Core Sampler® and associated parts.
- 4.10.1.2 Pre-probe point and rods implemented in its use.

4.10.2 Aqueous Sampling Decontamination Steps:
- 4.10.2.1 Detergent plus tap water wash
- 4.10.2.2 Generous tap water rinse
- 4.10.2.3 DI water rinse
- 4.10.2.4 Nitric acid rinse (if sampling for metals)
- 4.10.2.5 DI water rinse
- 4.10.2.6 Acetone rinse (if sampling for organic parameters)
- 4.10.2.7 Total air dry
- 4.10.2.8 DI water rinse

4.10.3 Non-Aqueous Sampling Decontamination Steps:
- 4.10.3.1 Detergent plus tap water wash
- 4.10.3.2 Generous tap water rinse
- 4.10.3.3 DI water rinse

5 GEOPROBE SAMPLING FOR SOILS:

5.1 Sampling with the Macro Core Sampler: The Macro Core sampler is a steel tube that measures two inches in diameter by forty-eight inches in length. The complete assembly consists of the tube, a cutter shoe, a liner tube, and a drive head that is connected to drill rod and advanced into the soil strata. The liner is manufactured of Polyethylene Tera-Phthalate Glycol (PETG) material as well as other materials. The liner is one point seventy-five inches diameter and forty-six inches long. It can hold up to approximately thirteen hundred milliliters of soil when full recovery is obtained. The sampler is decontaminated (Ref.4.10.3), put together and introduced into the soil from zero grade and driven to the desired depth. The sampler is meant to be used mainly as a open advanced bore-hole system. The sampler is pushed and/or percussion hammered into the soil, extracted out of the soil, and opened.

5.2 Sampling Procedures: After the sampler is extracted out of the bore-hole, the liner is removed, cut open and the soil from pre-determined depths are then placed in sample containers. Initial sampling includes the collection of soil samples from the 0-6 inch interval within each bore-hole. Subsequent samples will be taken at alternating 6-inch intervals to a depth of 186 inches. In the event a sample result collected at the 180-186 interval exceeds the New Jersey Residential Direct Contact Soil Cleanup Criteria for PCB, additional samples will be collected within the appropriate borehole for the purpose of establishing a complete vertical delineation. Field notes are written as to note soil structures, colors and any other materials. Odors and any other factors regarding the sample are noted as well.

6 GEOPROBE SAMPLING FOR GROUNDWATER:

6.1 Ground Water Sampling with the use of a Passively Placed Narrow Diameter Point (PPNDP): A narrow diameter point (PPNDP) is a small diameter («-1 inch OD) screened casing passively placed in a bore-hole. A solid push rod (pre-probe) is used to create a narrow diameter hole to a depth below the water table. This is performed with a rotary hammer. A piece of schedule 40 PVC screen with 0.010-inch slots and an end cap is placed at the bottom of each bore-hole from the point where the last soil sample was collected. No filter or gravel pack is used in the construction of each well sampling point. Each well point is utilized for period of less than 48 hours.

6.2 Installation: Within each bore-hole, commencing from the point where the last soil sample is collected, the pre-probe is driven to a depth of 1-3 feet below the water table. The screened section of PVC is placed into the borehole so the screened interval was across the ground water table. Prior to installation of the PPNDP, knowledge of the depth to water is established from previous soil sampling activities.

6.3 Sampling Procedure: Three to five volumes of the standing water in the PPNDP are purged prior to sample collection. This is accomplished utilizing a peristaltic pump. The tubing used for the well purging is food grade polyethylene and silicon surgical tubing that is discarded after each purging event. The tubing utilized for well purge activities will also be used for the collection of groundwater samples. Upon completing well purge activities, the tubing will be inserted into the appropriate sample bottle and filled to the required amount. Following sample collection, the PVC screen is removed from each borehole. Granular bentonite will then added to a level just above the saturated zone. Soils previously removed during sampling activities will then be reintroduced back into each borehole and compacted.

6.4 Quality Assurance/Quality Control: The PPNDP and associated equipment (bull point, riser pipe, etc.) are decontaminated between borings using the following procedure: 1) Removed all adherent soil material. 2) Washed with a laboratory grade glassware detergent. 3) Rinsed with potable water. Rinsed with distilled and de-ionized ASTM Type II water. Field blanks are obtained in the same manner as the sample. The blank water is passed through the sample device and the PPNDP prior to installation, then into the sample container. The parameters and frequency for field blanks are designated in the May 1992 edition of the NJDEP Field Sampling Procedures Manual.

7 QUALITY CONTROL:

7.1 QA/QC samples are intended to provide control over the collection of environmental measurements and subsequent validation, review and interpretation of generated analytical data.

7.1.1 The purpose of a field blank is to place a mechanism of control on sample equipment handling, preparation, storage and shipment. Field blanks travel with and are stored with the sample bottles. Field blanks are collected in the following manner. Two identical sets of bottles are prepared. One set is filled with laboratory demonstrated analyte free water. All of the filled bottles are

shipped with the other empty sample containers. At the field location, in an area where contamination is suspected, the water is passed from the full set of like-bottles through the dedicated or field decontaminated sampling device and into the empty set of like-bottles. Field blanks are preserved identically to samples receiving the same analyses. Field blanks are collected and analyzed for all of the same parameters as the samples collected that day.

7.1.2 Duplicate sample collection. For aqueous samples, duplicates are taken by alternating filling containers from the same sampling device for each of the required parameters. For non-aqueous matrices, obtaining duplicates requires homogenization of the sample aliquot prior to filling sample containers. Duplicates are taken at the rate of one per twenty.

STANDARD OPERATING PROCEDURE

SOP No.: SAM-0211
Revision No.: New
Date Revised: 3-24-99

CATEGORY: Sample Handling
TITLE: Geoprobe Sampling Methods for Site M-2 Landfill Cover Investigation

1 PURPOSE: To document the procedures used for sample collection.

2 RESPONSIBILITY: Designated field sampler properly instructed and trained in field sampling protocol and techniques.

3 REFERENCES:

3.1 Field Sampling Procedures Manual, May 1992. New Jersey Department of Environmental Protection.
3.2 Geoprobe Tools and Equipment Catalog 98/99.

4 SUMMARY: This SOP represents all general field sampling requirements as required by the NJDEP. It specifically addresses the proper use of protective equipment, collection of QA/QC samples, field decontamination procedures, proper documentation of all field activities, collection of samples into proper containers with the proper preservation and the techniques for collecting each type of sample.

4.1 The employee shall use personal protective equipment (PPE) for adequate protection and to limit the level of exposure on site. The equipment selected is appropriate to protect against all known and potential hazards. All field personnel are familiar with the potential hazards that may be encountered on site prior to entry.

4.2 At a minimum, all field personnel will don work boots (steel toe construction), safety glasses, and gloves available for all sampling activities. Standard latex surgical gloves are worn at all times when samples are collected or handled.

4.3 Proper documentation of all site activities is crucial. Documentation is maintained to trace the possession and handling of samples from the time of collection, through analysis and disposal.

Prepared By _____ Date 3-24-99

Approved By _____ Date 3-24-99
QA Manager / ~~Laboratory~~ Director

4.4 The field sampler will maintain a bound field-sampling logbook with permanently numbered pages. All field activities and notes are documented in this book. Notations are made in logbook fashion, noting the time and date of all entries. Information recorded in the logbook includes name and location of site investigation, date and time of arrival and departure, persons contacted, weather conditions, samples taken, method and time of collection and depths if required. Field instrument calibrations are kept in separate books.

4.5 Sample containers are labeled after sample collection. Sample labels include the following: well or sample number, parameters, preservatives, date and time of sample collection, sampler's initials and site name/location.

4.6 The sample containers are listed below:
4.6.1 (1) Two-ounce clear glass containers with Teflon lined lids.
4.6.2 (1) Two-ounce clear glass containers with septum.
4.6.3 (2) Four ounce clear glass containers w/o septum, with Teflon lined lid.

4.7 A chain of custody (COC) form is completed in the field and accompanied each set of samples collected. The COC is a legal record of possession of the samples and of request for analysis. It bears the name of the person assuming responsibility of the sample. A copy of a chain of custody can be found in SOP No. SAM-0201 Attachment 2 (Sample Receiving, Log-In and Disposal).

4.8 Sample techniques are accomplished as follows:

4.8.1 The Macro Core Sampler ® is utilized in the extraction of the soil samples (Ref.5.1). The soils are taken using the methanol extraction method (Ref.SAM 0207).

4.9 Samples are properly preserved and the correct size, shape and color containers are used. Guidelines for sample containers and preservation can be found in SOP No. SAM-0200 (Sample Containers, Preservation and Holding Time).

4.10 Equipment List:

4.10.1 Geoprobe Macrocore Sampler® Assembly

4.11 Decontamination Procedures for Field Sampling Equipment

4.11.1 Items de-contaminated are as follows:

4.11.1.1 Macro Core Sampler® and associated parts.

4.11.2 Non-Aqueous Sampling Decontamination Steps:

4.11.2.1 Detergent plus tap water wash
4.11.2.2 Generous tap water rinse
4.11.2.3 DI water rinse

5 GEOPROBE SAMPLING FOR SOILS:

5.1 Sampling with the Macro Core Sampler: The Macro Core sampler is a steel tube that measures two inches in diameter by forty-eight inches in length. The complete assembly consists of the tube, a cutter shoe, a liner tube, and a drive head that is connected to drill rod and advanced into the soil strata. The liner is manufactured of Polyethylene Tera-Phthalate Glycol (PETG) material as well as other materials. The liner is one point seventy-five inches diameter and forty-six inches long. It can hold up to approximately thirteen hundred milliliters of soil when full recovery is obtained. The sampler is decontaminated (Ref.4.11.2), put together and introduced into the soil from zero grade and driven to four feet. The sampler is meant to be used mainly as a open advanced bore-hole system. The sampler is pushed and or percussion hammered into the soil, extracted out of the soil, and opened up.

5.2 Sampling Procedures: After the sampler is extracted out of the bore-hole the liner is removed, cut open, and screened with a photo ionization instrument (HNU®) and or a flame ionization (OVA®), upper zone samples are taken from the area directly below any organic root material from grasses or tree roots. In most instances this sample is taken from 6-12". Volatile samples are taken using the methanol extraction method (REF.SAM 207) at a depth of 24". This sample is taken as soon as possible so that the soil does not volatilize. Additional organic samples may have be taken for sections with detectable readings. Field notes are written as to note soil structures, colors and any other materials. Odors and any other factors regarding the sample are noted as well.

5.3 Quality Assurance/Quality Control: All equipment is decontaminated between borings using the following procedure:

5.3.1 Remove all adherent soil material.
5.3.2 Wash with a laboratory grade glassware detergent.
5.3.3 Rinse with potable water.
5.3.4 Rinse with distilled and deionized ASTM Type II water.

6 QUALITY CONTROL:

6.1 QA/QC samples are intended to provide control over the collection of environmental measurements and subsequent validation, review and interpretation of generated analytical data.

6.1.1 The trip blanks are used exclusively for volatile organic analysis. Its purpose is to measure possible cross contamination of samples during shipping to and from the site. The trip blank is never opened and travels to the site with the empty sample bottles and back from the site with the collected samples. Contaminated trip blanks may also indicate bottle cleaning of questionable quality. Trip blanks are included at the rate of one per day.

6.1.2 Duplicate samples are required. For non-aqueous matrices, obtaining duplicates requires homogenization of the sample aliquot prior to filling sample containers. Regardless, volatile organic samples must always be taken from discrete locations or intervals without compositing or mixing. Duplicates are taken at the rate of one per twenty.

CATEGORY: Sample Handling
TITLE: Monitor Well Sampling for IRP Sites at Fort Monmouth

1 PURPOSE:

To document current procedures for monitoring well sampling.

2 RESPONSIBILITY:

Designated field samplers who have been properly trained and instructed in NJDEP field sampling procedures and protocol.

3 REFERENCES:

3.1 Field Sampling Procedures Manual, May 1992 (most current). New Jersey Department of Environmental Protection and Energy.

3.2 Occupational Safety and Health Guidance Manual for Hazardous Waste Site Activities developed by NIOSH, OSHA, USCG, EPA. Oct. 1985

3.3 NJDEP Field Analysis Manual, July 1994.

3.4 On the World Wide Web: www.state.nj.us/dep or www.state.nj.us/dep/srp.

3.5 Lab SOP: SAM-0200, SAM-0202, OQC-0302

4 SUMMARY:

The procedures, materials, and equipment describe the recommended methods for sampling monitoring wells. Necessary equipment, calibrations, calculations and appropriate QA/QC procedures are also included. These procedures are to be followed by all personnel involved with the sampling and purging of wells at Fort Monmouth. Persons following this SOP are recommended to also refer to the NJDEP Field Sampling Procedures Manual.

Prepared By _____ Date 8/9/99

Approved By _____ Date 8/9/99
QA Manager / Laboratory Director

5 EQUIPMENT AND MATERIALS:

5.1 Equipment

5.1.1 Dissolved oxygen meter
5.1.2 HNU photo ionizer
5.1.3 Conductivity/pH/temp meter
5.1.4 Peristaltic well pumps
5.1.5 Pump heads and power cables
5.1.6 Water level meter
5.1.7 Oil/water interface probe
5.1.8 Submersible well pumps
5.1.9 Various batteries
5.1.10 Buckets
5.1.11 Miscellaneous tools, i.e. screwdriver, well wrench, etc.

5.2 Materials:

5.2.1 Thick wall silicone tubing ¼ inch diameter,
5.2.2 Polyethylene (food grade) tubing ¼ inch diameter,
5.2.3 12 inch single sample 1 check stop teflon disposable bailers,
5.2.4 Mason string.

6 STANDARDS/REAGENTS:

6.1 Buffer solutions, calibration gases, decontamination materials, and acids for preservation.

6.1.1 Buffer solutions:
6.1.1.1 7.00 standard buffer solution
6.1.1.2 10.00 standard buffer solution
6.1.1.3 4.00 standard buffer solution
6.1.1.4 Distilled and deionized water
6.1.1.5 Alconox
6.1.1.6 10 % nitric acid rinse (trace metal or higher grade HNO3 diluted with distilled/deionized (ATSM Type II) H2O)
6.1.1.7 Acetone (pesticide grade)
6.1.1.8 Pure nitrogen 100 ppm Isobutylene calibration gas.

6.1.2 Acids/materials used in preserving samples:

6.1.2.1 Nitric acid 69, 0-70.0%
6.1.2.2 Sulfuric acid 50% (w/w) solution
6.1.2.3 Hydrochloric acid (trace metal grade)
6.1.2.4 Ice for keeping samples at <4 degrees celsius.

Refer to NJDEP Field Sampling Procedure Manual Table 2-1 Aqueous Sampling Equipment Decontamination (Lab and Field).

7 CALIBRATION:

All instruments used for field readings are calibrated before each day of use. The use of pH meters must start out with a calibration using buffer solution standards to check or calibrate accuracy. HNU's are calibrated with a known calibration gas. Dissolved oxygen meters are checked against a Winkler method test weekly. All calibrations for a given day's use are recorded in the log provided for each instrument. Refer to equipment directions for calibration instruction. Likewise, specific conductivity meters are checked against standards regularly. Cooler thermometers are calibrated against an NIST traceable thermometer annually.

8 PROCEDURE:

The following articles document the procedures for sampling monitor wells. They are to be used as a guide, by trained personnel, in conjunction with the NJDEP Field Sampling Procedures Manual.

8.1.1 Preparation: It should be noted that before going out into the field, certain preparations must be made. This includes the selection of PPE, safety plans, proper bottle acquisition for analytes being tested, site entry, map information, and equipment.

8.1.2 Selection of personal protective equipment (ppe): For adequate protection and prevention of contaminant exposure to workers at hazardous waste sites in all phases of work, PPE is properly used and supplied. Determination of PPE will be outlined in a Health and Safety Plan, and also by preliminary site investigations. Refer to NJDEP Field Sampling Procedures Manual, and the Occupational Safety and Health Guidance Manual for Hazardous Waste Site Activities.

8.1.3 Health and Safety Plans: These plans are developed to encompass all the aspects of site operations. Plans are available to personnel associated with site sampling and a copy is kept on file at the site (in this case, the laboratory). At a minimum, the plan includes all portions of Site Remediation Program's (SRP) Site Safety and Health Standard Operating Procedures deemed appropriate for site, detailed site description, emergency phone numbers, a map and directions to nearest hospital identified on the map, and all PPE needed.

8.1.4 Proper bottle selection: Please refer to QA/QC section 10.1.

8.1.5 Equipment: Please refer to Equipment section 5.

8.1.6 Before purge activities: Certain instruments and meters are calibrated before use. Also, certain measurements and calculations are obtained before any purge activities take place. The following is a list of information/data/steps required prior to the commencement of purge activities. Pertinent information is recorded in logbooks or on well sheets.

8.1.7 Date, time and weather conditions: Date and time are needed for holding time purposes and general record keeping. Weather conditions may affect ambient conditions at a particular site, therefore said information is recorded. Tidal influences may also be included here, if wells are in a tidal area.

8.1.8 Well number and permit number: These are prominently displayed on the outside of each well in accordance with NJDEP regulations for well construction.

8.1.9 Meter and instrument calibrations: Meters utilized in the course of site sampling activities are calibrated at this time, and the findings recorded in the appropriate logbook. Refer to section 7 for instrument/meter calibration directions.

8.1.10 PID or FID, HNU reading: This is taken from the well inner casing immediately after the cap is removed, findings are recorded.

8.1.11 Free product check: Using ORS interface meter for interfaces, the presence or absence of free product is determined. Thickness is measured and recorded.

8.1.11.1 Light Non-Aqueous Phase Liquids (LNAPLs) and Dense Non-Aqueous Phase Liquids (DNAPLs): Measurement of thickness for DNAPLs and LNAPLs are performed prior to well purging. An interface probe is used (ORS meter) for this task. If present, LNAPLs are sampled and analyzed for chemical and physical parameters. Sampling is conducted by using a bottom filling bailer which is lowered into the LNAPL layer. DNAPLs are sampled using a dual check valve bailer. If present, DNAPLs are also tested for chemical and physical properties.

8.1.12 Dissolved oxygen, pH, temperature, and specific conductivity: Readings are obtained and recorded on well sheets.

8.1.13 Total depth of well and depth to water: These readings are taken using a depth meter. Total depth of well, depth to water, and depth to screen are measured from the top of the inner casing or surveyors mark. All data is recorded on well sheet.

8.1.14 Calculations: Calculations are made as stated in section 9.

8.2 Purging: When pre-purge activities are complete, the purging of a well can begin. This includes pre-entry to the well and pump setup.

8.2.1 Pre-entry to well: Before tubing (refer to materials section) is inserted into a well, it is wiped down and rinsed with DI water. The tubing is then inserted into the well to a maximum depth of six feet below the water table. During purge activities, the depth of the tubing may be adjusted to prevent the static water level from dropping below the end of the tubing.

8.2.2 Pump setup: Once the battery powered peristaltic pump is set up, purging can begin. Evacuation rates never exceed that of well development, and total volume purged never exceeds 5 times the amount of standing water. Purge water management practices are described in section 10.1.8.

8.3 After Purge: When purging is complete, the pump is removed and tubing is disposed of properly. Data referenced in section 8.3.2 is then taken and recorded.

8.3.1 Pump removal: Tubing is removed from the bottom end while the pump is still running. Tubing is then disposed of. The pump is shut down and decontaminated for its next application.

8.3.2 The following data is recorded on the well sheet: Start and end time of purge, purge method, purge rate, total volume purged, dissolved oxygen, pH, temperature, and specific conductivity readings.

8.4 Field Blank Sample: At this time the field blank sample is collected. A new bailer is opened from its sealed package and field blank water is run over the bailer or sample equipment and collected into the proper sample containers.

8.5 Ground water sampling: Following well evacuation procedures, ground water sampling can begin. In most cases, sampling takes place immediately following purge activities. However, due to certain field conditions, well sampling may be postponed for a period not to exceed 2 hours following completion of purge activities. When multiple wells are being sampled, the least contaminated well is sampled first. Subsequent wells are sampled in order of ascending contamination. Sampling is conducted by using a bottom filling Teflon bailer, dedicated to each particular monitoring well. The bailer is lowered slowly into water column until submerged, and then slowly retrieved. The sample is then carefully transferred to the appropriate sample containers. Ground water collected in the first bailing sequence is always used for sampling purposes, it is never discarded.

8.6 Sample order: Samples are collected in the following order:

8.6.1 volatile organics (VOA)
8.6.2 purgeable organic carbons (POC)
8.6.3 purgeable organic halogens (POX)
8.6.4 total organic halogens (TOX)
8.6.5 total organic carbon (TOC)
8.6.6 base neutrals/acid extractables
8.6.7 TPHC/oil and grease
8.6.8 PCB's/pesticides
8.6.9 total metals
8.6.10 dissolved metals

8.6.11 phenols, cyanide
8.6.12 sulfate and chloride
8.6.13 turbidity
8.6.14 nitrate and ammonia,
8.6.15 preserved inorganics
8.6.16 radionuclides
8.6.17 non-preserved inorganics
8.6.18 bacteria

8.7 Dupes and matrix spikes/matrix spike duplicates: These samples are taken in same order at same time. Refer to section 10.2.1.2.

8.8 After sampling: The following data is recorded on well sheets: Start and end time of sampling, dissolved oxygen, pH, temperature, specific conductivity, and sampling method.

9 CALCULATIONS:

Four calculations are made while in the field. The calculations are as follows: linear feet of water (height of water), the volume to be purged, the volume purged not to be exceeded, and purge rate.

9.1 Linear feet of water: This is calculated by knowing the total depth of a well and subtracting the depth to water as measured by a depth meter. These two numbers are measured to within .01 feet. Through this calculation, the linear feet of water is determined.

Equation: (Total well depth – Depth to water = linear feet of water)

9.2 Volume to be purged and volume not to be exceeded: The second calculation is to determine the minimum volume to be purged from a well before sampling. Utilizing the linear feet of water and then multiplying it by the volume per foot for the proper diameter casing (see Figure 1 below) equals the amount of water in casing. Multiplying the amount of water within a casing by 3 equals the minimum volume to be purged. It should be noted that the amount purged should not exceed 5x the amount of standing water in a well.

Equation:

linear feet of water x volume per ft for well diameter = amount of water in casing)
then,
(amount of water in casing x 3 = minimum volume to be purged)

Equation:

(amount of water in casing x 5 = total volume not to be exceeded)

Figure 1: Capacity of Common Casing Diameters
(Pp. 170 in NJDEP (FIELD SAMPLING PROCEDURE MANUAL)

Casing Diameter (ft.)	Gallons/linear foot
2 inch (0.1667)	0.1632
4 inch (0.3333)	0.6528
6 inch (0.5000)	1.4688
8 inch (0.6667)	2.6112
10 inch (0.8333)	4.0800
12 inch (1.0000)	5.8752

9.3 Purge rate: The purge rate is determined by calculating the length of time it takes for a pump to fill a 1-gallon bucket with water. The time is then multiplied by the minimum volume to be purged. The gallons being purged is then divided by this number (which also happens to be the length of time the purge will take in minutes) which equals the gallons per minute or purge rate.

Equation:

(time x minimum volume to be purged = length of purge in minutes)
then,
(minimum volume to be purged / length of purge in minutes = gallons per minute or the purge rate)

10 QUALITY CONTROL:

The following QA/QC requirements are established in order to maintain sample integrity. The prime objective is to prevent sample contamination from other sources and ensure potential contaminant concentrations remain stable from sample collection to complete

analysis. Refer to the NJDEP Field Sampling Procedures Manual Appendix 2-1 Analytical Methodology Reference Charts, Pp. 24-74. Also refer to SAM-0200 Sample Containers, Preservation and Holding Times.

10.1 Sample Containers: Before sample collection can begin consideration must be given as to what type container will be used to transport and store samples. The lab provides containers based upon requested methodologies. Selection is based on the matrix, potential contaminants, analytical methods, and the laboratory's internal QA/QC requirements. They are selected upon review of the following:

10.1.1 Reactivity of container material with sample. Glass is recommended for hazardous material samples since it is chemically inert to most substances. Plastics may be used when analytes of interest or sample characteristics dictate use instead of glass.

10.1.2 Volume of the container. The volume of sample needed is dictated by the analytical method and the sample matrix. The laboratory supplies bottles that allow for sufficient volumes of sample matrix to be collected.

10.1.3 Color of container. Whenever possible, amber glass is used to prevent photodegradation. If not available, samples are protected from light. One exception is the use of 40 ml clear glass vials which are used for VOA/aqueous analysis.

10.1.4 Container closures. All containers utilized have a leak-proof seal and are constructed out of inert material with respect to sampled materials. The closure may also be separated by a closure liner that is inert to sample material.

10.1.5 Decontamination of containers and chain of custody. Sample containers are laboratory cleaned or purchased as lab cleaned. Bottles being shipped are accompanied by a chain of custody in a cooler with a custody seal. Custody always accompanies containers to the field, during collection, back to lab, and during analysis. This helps to assure no tampering or contamination from outside sources occurs.

10.1.6 Storage and transport. Care is taken to avoid contamination. Clean transport and storage environments are observed. Sample or bottle storage is never near solvents, gasoline, or other equipment that is a potential source of

contamination. Samples and chain of custody are secured in coolers or transport, with said chain of custody in with bottles or in the possession of authorized personnel. Also, a temperature blank is included in each cooler to measure temperature of samples on ice (ideally a constant 4 degrees Celsius).

10.1.7 Tubing decontamination: ASTM drinking water grade polyethylene tubing is used and discarded after each use. Care is taken to prevent the pump and tubing from coming into contact with the ground surface. Prior to well purging, all tubing is rinsed/wiped with distilled and deionized water to remove any possible residual materials which may be present.

10.1.8 Disposal of development, purge, pump test, and decon waters: To determine whether waste waters are contaminated, field instrument readings and previous analytical data is used to characterize it. Water not considered contaminated is re-applied directly to ground surface and permitted to percolate back to the water table. Care is taken to avoid nuisance situations where a discharge may cause undue concern. When water is considered contaminated, the water generated is reapplied only if the following conditions are met: ground water is not permitted to migrate offsite, no potential exists for contaminating a previously uncontaminated aquifer, discharge will not cause an increase to ground surface soil contamination. If these conditions are met, the water is re-applied to the ground surface. If these conditions aren't met, than water is collected, containerized and secured in a single locale. Subsequently, the water is properly characterized and processed for offsite disposal.

10.2 QA/QC samples: These samples are intended to provide control over the collection of environmental measurements and subsequent validation, review, and interpretation of analytical data. Trip blanks are used exclusively for volatile organic analysis, (aqueous sampling only) and their purpose is to measure possible cross contamination of samples during shipment to and from a site. Trip blanks are never opened and travel to a site with the empty sample bottles and back from a site with the collected samples. Contaminated trip blanks may indicate bottle cleaning or blank water of questionable quality. Trip blanks are collected at the rate of one per day. Likewise, the purpose of a field blank is to place a mechanism of control on sample equipment handling, preparation, storage and shipment. Field blanks travel and are stored with the sample bottles. Field blanks are collected in the following manner. Two identical sets of bottles are

prepared. One set is filled with laboratory demonstrated analyte free water (same water used for trip and method blanks). All of the filled bottles are shipped with the other empty sample containers. At the field location, in an area where contamination is suspected, the water is passed from the full set of like-bottles through the dedicated or field decontaminated sampling device and into the empty set of like-bottles. Field blanks are preserved identically to samples receiving the same analyses. Field blanks are collected and analyzed for all of the same parameters as the samples collected that day.

10.2.1 Additional QA/QC samples:

10.2.1.1 Duplicate samples: Collection of a dupe provides for evaluation of laboratory performance by comparing the analytical data of two samples from the same location. They are included 1 for every 20 samples (5% or 1 a day/site) and submitted as blind samples. They are obtained by alternately filling sample bottles from the same source/device for each parameter. VOA samples are same bailer and first set filled.

10.2.1.2 Matrix spike/Matrix spike duplicate analyses or MS/MSDS sample: The laboratory is supplied with triple volume in order to perform matrix spike and matrix spike dupes. This does not include trips or field blanks. Additional sample volume for MS/MSDS is taken within every set of 20 field samples.

10.3 Sample preservation: Sample bottles are preserved by lab staff based upon analytical requirements. Please refer to SAM-0200 Sample Containers, Preservation, and Holding Times SOP and also NJDEP Field Sampling Procedures Manual Appendix 2-1 Analytical Methodology reference Charts, Pp. 24-74.

STANDARD OPERATING PROCEDURE

SOP No.: SAM-0207
Revision No.: New
Date Revised: 7-3-99

CATEGORY: Sample Handling
TITLE: Field Sampling / Methanol Extraction

1 PURPOSE: To document the current procedures for sample collection using the Methanol Extraction Method.

2 RESPONSIBILITY: Designated field samplers who have been properly instructed and trained in field sampling protocol and techniques.

3 REFERENCES: NJDEP Methodology for the Field Extraction/ Preservation of Soil Samples with Methanol for Volatile Compounds. February 1997.

4 SUMMARY: This method describes the container preparation,field sampling and field extraction/preservation procedure to be used in conjunction with the analysis of soil samples for volatile organics.

4.1 Soil samples collected for volatile organic analysis must be handled in a manner which will minimize the loss of contaminants due to volatilization and biodegradation. Field extraction/preservation with methanol must be conducted to ensure that contaminants do not degrade or volatilize during sample handling and transport.

4.2 A small diameter soil core sampling device is used to collect a 10 gram soil sample.The sample is extruded into a tared sample container, supplied by the laboratory performing the analysis.

5 SAMPLE COLLECTION METHODOLOGY:

5.1 Soil sample collection for volatile organic analysis must be performed with the use of a decontaminated small diameter coring device. A modified 10-30 ml disposable syringe or commercially available small diameter tube/plunger sampler is acceptable. The small diameter coring device must be capable of collecting the required amount of sample from larger diameter core samplers (split spoons, etc.) or from freshly exposed soils.

Prepared By _____ Date 7-7-99

Approved By _____ Date 7-3-99
QA Manager / Laboratory Director

5.2 If a modified disposable syringe is used it can be prepared in-house by cutting off the injection tip. Depending upon the construction of the syringe, small air vents must be cut into the plunger or if a modified disposable syringe is used it can be prepared in-house by cutting off the injection tip. Depending upon the construction of the syringe, small air vents must be cut into the plunger or the rubber tip and retaining post must be removed. These alterations to the plunger will prevent air from being forced through or around the soil plug during subcoring and sample extrusion.

5.3 The small diameter core sampler must be capable of delivering the sample directly into the sample container. The outer diameter of the core sampler must be smaller than the inner diameter of the sample container to avoid loss of sample and ease the soil transfer process.**The sample from the small diameter core cannot be transferred to a secondary container such as another sample bottle, zip lock bag, aluminum foil, etc. prior to placement into the sample container with the methanol preservative.**

5.4 Use a small electronic balance or manual scale for measuring the weight of the soil in the syringe. The scale must be calibrated before use, and intermittently the calibration should be checked during the sampling day to ensure accuracy of the weight measurements.

5.5 Tare weigh the small diameter core sampler

5.6 Once the sampling interval has been selected, trim off the surface soils of the sample interval to expose a fresh soil surface. The loss of volatile organics from the surface soils will occur if the soil has been exposed for a short period of time (during screening, etc.). The removal of the surface soils can be accomplished by scraping the soil surface using a decontaminated spatula or trowel The sampling procedure must commence immediately once a fresh soil surface has been exposed.

5.7 Using a decontaminated coring device, collect 10g ≯2g (8-12grams) of sample (wet weight). Wipe the outside of the subcoring device to remove any adherent soil. The plunger of the coring device can be pulled back or completely removed allowing the open barrel of the subcore to be inserted into the soil. Depending upon the soil texture, depth or moisture content, the subcore can be inserted straight into the soil, on an angle or multiple insertions can be performed to obtain the required sample weight.

5.8 Quickly weigh the sample while contained in the small diameter core sampler. Excess soil sample can be removed from the coring device by extruding a small portion of the core and cleaning away with a decontaminated trowel or spatula. **If soil weight is below**

the weight limit, obtain additional sample. Reweigh after each addition or removal of sample to the subcore until the target weight is attained (8-12g). Analytical results from a sample exceeding the weight maximums and minimums may be rejected and thus require resampling.

5.9 When sampling soils consisting of similar textures and water content, sample weight can be estimated based on volume of previously weighed samples from sampling or practice core sampling to determine sample weights.

5.10 Immediately open the sample container and slowly extrude the soil core into the preweighed and prenumbered sample container supplied by the laboratory performing the analysis. Avoid splashing methanol out of the sample container. Do not insert the small diameter coring device into the mouth of small diameter sample containers (40ml or 60ml VOA vials) or immerse the small diameter soil coring device into the methanol.

5.11 Ensure the threads on the sample container and cap are free of soil particles. Use a clean brush or paper towel to remove the particles off the threads. The presence of soil particles compromises the seal of the container resulting in loss of methanol which may invalidate the sample.

5.12 Secure the lid of the sample container. Gently swirl the sample to mix and break up the soil aggregate until soil is covered with methanol. **Do not shake.**

5.13 Do not attach any additional adhesive backed labels or tape to the sample containers. Record sample numbers on container avoiding covering laboratory identification number. Labels with wire or rubber band attachments may be used provided they can be removed easily for sample weighing. Record laboratory and field identification numbers on chain of custody and field notes.

5.14 The actual weight of soil will be determined by the laboratory performing the analysis.

5.15 Do not use or submit samples for analysis if any methanol has spilled from a sample container during shipment to the site or during sampling. Extra sample containers can be made available by the laboratory in case of accidental spillage of methanol in the field.

5.16 After sample collection, immediately return the containers to an iced cooler in an upright position. Sample containers can be placed in separate ziplock bags to protect other containers in case of leakage during transport. The laboratory sample number or field sample identification number may be placed on the bag and crossed referenced on the Chain of Custody. Do not place additional adhesive backed labels or tape on the sample containers. If any methanol is lost from a sample container upon arrival at the laboratory, the sample is invalid and resampling must be performed.

6 MOISTURE DETERMINATION:

6.1 To report the sample results on a dry weight basis, collect one duplicate sample **not preserved with methanol** from each sample location for moisture determination. Tightly seal the container to prevent the loss of soil moisture. This sample does not require to be weighed or preserved with methanol. This is taken for a percent solids analysis and a two ounce container is sufficient for this sample, it is taken for each methanol sample taken including duplicates.

7 QA/QC SAAMPLE AND DECONTAMINATION REQUIREMENTS

7.1 **The collection of an Ambient Blank is not required when sampling is performed using the methanol extraction/preservation technique**. It will be optional at the discretion of the site investigation team, or will be required on a site specific basis if previous elevated analytical results are suspected due to contamination from the sampling environment.

7.2 If Ambient Blanks are employed, the frequency of collection should be one (1) per day or at the discretion of the investigation team based on site conditions.

8 FIELD BLANK:

8.1 A Field Blank is a QA/QC sample which will determine potential contamination from sampling equipment used to collect and transfer samples from the point of collection to the sample container.

8.2 **A Field Blank is not required when sampling with the methanol extraction/preservation technique.** It is optional, or will be required on a site specific basis if previous elevated analytical results are suspected due to cross contamination from sampling equipment.

8.3 A Field Blank is performed by pouring demonstrated analyte free **water** from one sample container, over each piece of sampling equipment required for sample collection and into a separate set of identical sample containers. Additional information on Field Blanks can be found in the NJDEP Field Sampling Procedures Manual, May 1992.

9 TRIP BLANK:

9.1 A Trip Blank is a QA/QC sample which will determine additional sources of contamination that may potentially influence the samples. The sources of the contamination may be from the lab, sample bottles or during shipment.

9.2 **A Trip Blank is required when sampling with the methanol extraction/preservation technique.** It will be required due to potential cross contamination from sample shipment or from handling at the laboratory.

9.3 A Trip Blank is prepared at the same time and in the same manner as the sample containers as described in Section 4.0. The Trip Blank must accompany the sample containers to the field and back to the laboratory along with the collected samples for analysis. It must remain sealed at all times until it is analyzed at the laboratory.

9.4 The frequency of collection for the Trip Blank must be at a rate of one (1) per sample shipment.

10 DUPLICATE SAMPLES:

10.1 Perform duplicate samples at a rate of five (5) percent (1 per 20 samples).

10.2 Duplicate samples must be obtained from the same location and soil type to minimize location as a potential source of variation in the analytical results. Separate core samples should be obtained for the sample and duplicate sample.

11 SAFETY:

11.1 Methanol is a toxic and flammable liquid. Therefore, methanol must be handled with all safety precautions related to toxic and flammable liquids. Inhalation of methanol vapors must be avoided. Vials should be opened and closed quickly during the sample preservation procedure. Methanol must be handled in a ventilated area. Use protective gloves when handling the methanol vials. Store methanol away from sources of ignition

such as extreme heat or open flames. The vials of methanol should always be stored in a cooler with ice at all times.

CATEGORY: Sample Handling
TITLE: Sample Receiving, Log-In and Disposal

1 PURPOSE: To document the procedure for the handling of coolers, logging in samples and disposal within the laboratory.

2 RESPONSIBILITY: Designated laboratory or administrative personnel who have been properly instructed and trained in the log-in procedure shall be responsible for checking in samples.

3 REFERENCE: Standard Methods for the Examination of Water and Wastewater, 18th Ed., 1989.

4 SUMMARY:

4.1 Using the Master Logbook, assign the next consecutive number as the FMETL project number for the samples.

4.1.1 Open the cooler and immediately check and record the cooler temperature by measuring the temperature of the cooler blank (bottle of water transported with samples).

4.1.2 Record the cooler temperature on the SAMPLE RECEIPT FORM, (Attachment 1).

4.1.3 Inspect the cooler contents by completing the top section of the SAMPLE RECEIPT FORM - Preliminary Examination Phase.

4.1.3.1 Remove samples and verify against the chain of custody to insure documentation accuracy and completeness.

4.1.3.2 Verify field identification numbers against the CHAIN OF CUSTODY FORM, (Attachment 2).

Prepared By _____ Date 7/29/99

Approved By _____ Date 7/29/99
QA Manager / Laboratory Director

4.1.3.3 Assign each individual sample an FMETL ID # which is designated by the project number with a hyphenated suffix beginning with -.01, and increasing consecutively for each sample in the project.

4.2 Inspect the samples for breakage, preservation, and overall condition by completing the center portion of the SAMPLE RECEIPT FORM - Log-In Phase.

4.2.1 Any individual sample that requires acidic or basic preservation methods, determine its pH using pH paper.

4.2.2 Record the sample ID# and pH on the SAMPLE RECEIPT FORM.

4.3 In the event of any discrepancies with either the coolers or the samples, complete the laboratory corrective action memo in the lower section of the SAMPLE RECEIPT FORM.

4.3.1 Reference any discrepancies and document the corrective action taken (e.g. pH adjustment or re-attaching loose label).

4.3.2 Where corrective action requires notifying appropriate persons of the problem (e.g. for incorrect sample volumes or broken bottles that would require resampling), contact client or appropriate person immediately to resolve any discrepancies. Record the time and date of the notification on the lower section of the SAMPLE RECEIPT FORM and initiate a Corrective Action Report.

4.4 Record the required information on the CHAIN OF CUSTODY FORM:

4.4.1 Lab Sample ID#.

4.4.2 Date and time received.

4.4.3 Project information (e.g. number of samples received, type of analyses).

4.5 Information on all samples received will then be entered into a bound logbook. This logbook will be of ledger type with columns and numbered pages. Each sample logbook will be sequentially numbered and on the outside cover, the starting

date and sample numbers will be indicated. All entries will be made using a ballpoint pen with permanent ink. All errors will be crossed out with a single line and initialed. The following will be entered into the logbook:

4.5.1 Sample ID#
4.5.2 Site
4.5.3 Location
4.5.4 Sample Date/Time
4.5.5 Matrix
4.5.6 Sampler
4.5.7 Analysis
4.5.8 Comments

4.6 A job folder will then be created. The job folder will be kept, sequentially, in a designated filing cabinet. The folder will contain the original chain of custody, sample receipt form and any field notes or maps. Data will be inserted into the folder, as it becomes available.

4.7 Deliver the logged-in samples to the proper storage areas (designated refrigerators). Proper storage of all samples prior to preparation and analysis is critical to the determination of accurate and high quality analytical results. Samples that are not properly stored may suffer degradation, volatilization, or reaction.

Refrigerator #	Samples
1	Volatiles
2	Semivolatiles
3	Extractions
4	Sample Receipt
5	Extracts
6	Metals/Wet Chemistry

4.8 Store samples that may easily be contaminated by other samples (such as drinking water samples) in a refrigerator separate from one where more highly contaminated samples are stored.

4.8.1 Monitor the temperatures of storage refrigerators daily to ensure sample integrity (see OQC-0303).

4.9 Deliver a copy of the CHAIN OF CUSTODY FORM to the various departments to notify analysts of the presence of the samples.

4.10 Each analysis has specified limits on Holding Times (see SAM-0200).

4.10.1 For samples received within 72 hours of sampling or before one-half of the holding time period is expired (whichever is less), the analyst will initiate sample preparation and/or analysis within the prescribed holding times.

4.10.2 For samples arriving after this, the client will immediately be informed of the status of the sample and told whether preparation and/or analysis can still be performed within established holding times. If preparation or analysis within the designated holding times is impossible, the client will be contacted for further instructions.

4.11 Due to limited refrigerator space, samples will be removed after a 90-day period or when analysis is complete.

4.11.1 Soil samples are emptied and returned to the site location.

4.11.2 Unpreserved aqueous samples are returned to their effluent discharge.

4.11.3 Preserved aqueous samples are disposed of into a 55-gallon acid/aqueous drum.

4.12 All waste materials classified as hazardous are managed in accordance with the Fort Monmouth Hazardous Waste Management Plan.

Attachment 1

SAMPLE RECEIPT FORM

Date Received: _____ Lab Project ID#: _____

Site/Project Name: _____ Cooler Temp (d. C): _____

Received By: _____ Sign: _____
(print name)

Circle the appropriate answer

1. Did the samples come in a cooler ?	yes	no
2. Were the chain of custody papers filled out correctly and legibly?	yes	no
3. Did you sign the chain of custody in the appropriate place?	yes	no
4. Did all the labels agree with the chain of custody and in good condition?	yes	no
5. Were the correct containers and/or preservatives used for the tests indicated?	yes	no
6. Was a sufficient amount of sample sent for the tests indicated?	yes	no
7. Were bubbles absent from aqueous VOC sample containers?	yes	no

Fill out the following table for each sample bottle

Sample ID	pH	Preservative	Sample ID	pH	Preservative

CATEGORY: Sample Handling
TITLE: Sample Containers, Preservation and Holding Times

1 PURPOSE: To document the sample containers, preservation and holding times requirements.

2 RESPONSIBILITY: Quality Assurance shall be responsible for maintaining and updating the sample containers, preservation and holding times SOP. These updates will occur annually at a minimum or as the methods' requirements change.

3 REFERENCES: Field Sampling Procedures Manual, May 1992. New Jersey Department of Environmental Protection.

4 SUMMARY: The following table is a summary of the sample containers, method required preservation and holding times of various analytical parameters. The summary will provide information to field sampling personnel and laboratory analysts. Additionally, this summary will aid individuals involved with data validation, quality assurance and sample receiving.

Table 1

Parameter	Container	Preservation	Holding Time*	Method
VOA AQ	2-40 ml septum, G Teflon lined cap	HCL, to pH <2 Cool, 4°C	14 days	624 (4), 8260 (2)
VOA Non-AQ	2 oz wide, G Teflon lined cap	Methanol, Cool, 4°C	14 days	8260 (2)

Re: Low Flow Sampling - Site M2
Fort Monmouth Main Post
Tinton Falls, Monmouth County

Dear Mr. Fallon:

The NJDEP is in receipt of your letter of October 7, 1999 requesting our review of the low-flow ground water sampling procedures determined necessary for accurate delineation of the contamination at the M2 landfill site located on the Main Post. NJDEP comments are summarized.

COMMENTS

1. Low Flow sampling should incorporate the use of a flow-through cell. The intent of a flow through cell is to minimize interaction of the purge water with the atmosphere, and to keep the metering probes constantly bathed in fresh well water. Since it is desirable to limit residence time within the vessel, the volume of the vessel must be relatively small. Depending on atmospheric conditions/temperature, this would generate a potential for temperature fluctuations to occur which would affect the accuracy of field measurements (especially for DO, Temp, pH, etc.). A diagram of a flow through cell is provided on page *two*. The exact type and construction of the flow-through cell may vary, but the basic principles must be met as described below:

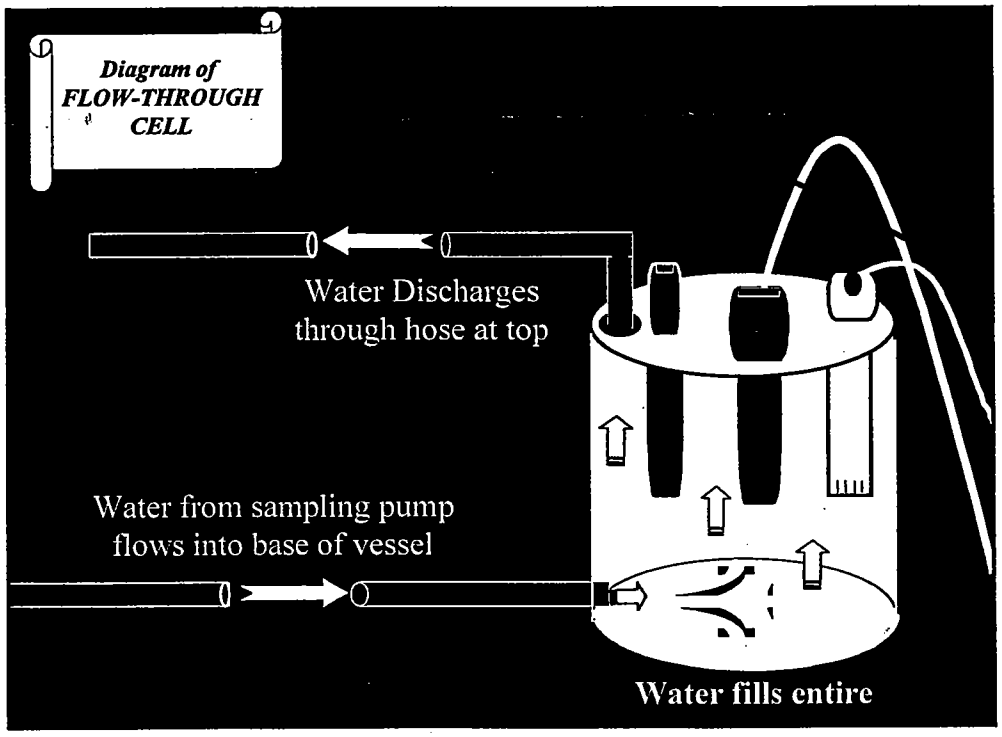
- Water enters from bottom and is forced out the top
- Metering probes are constantly bathed in fresh well water, and there is no significant headspace existing at the top of the vessel
- Cell should be relatively small to limit residence time.

2. The length of tubing between the well and the flow-through cell must be short to prevent heating or cooling of the sample prior to it entering the flow-through cell. In this respect, the flow-through cell and all metering devices should be situated in close proximity to the well.

3. Tubing diameter must be small ($\frac{1}{4}$ to $\frac{3}{8}$ inch) to prevent air bubbles from forming in the discharge line.

4. Ground water elevation measurements and total depth of well measurements must be obtained the day before sampling is actually conducted. The intent of this condition is to limit disturbance of the water column within the well, to obtain synoptic ground water elevation data, and to document well construction specifications prior to sampling (i.e., total depth of well).

5. No interruptions in flow, or adjustments to flow rate, should occur between purging and sampling once field parameters have stabilized.



Please note that due to the use of a peristaltic pump in the sampling process, the NJDEP only allows compounds with low volatility and metals to be sampled using this procedure.

If I can be of any further assistance, please do not hesitate to contact me at (609) 633-7232.

Sincerely

Ian R. Curtis, Case Manager

SUBJECT: Remedial Investigation of Landfill Site M2

Dear Mr. Curtis:

As part of an ongoing remedial investigation at landfill site M2, the Directorate of Public Works (DPW) has installed a total of ten shallow monitoring wells in order to evaluate ground water quality. During the site investigation phase of this project, four monitoring wells (four-inch diameter wells) were installed. To date, nine consecutive quarterly rounds of ground water samples have been collected from each of the four wells. The Standard Operating Procedure (SOP No.: SAM-0205) titled "Monitor Well Sampling for Installation Restoration Program (IRP) Sites at Fort Monmouth" which documents our sampling procedures is enclosed for your review and edification. Each sample was analyzed for Target Compound List (TCL) plus 30 parameters and Target Analyte List (TAL) metals. Based upon the presence of moderate levels of chlorobenzene within site ground water, the DPW was preparing to develop a Remedial Action Work Plan which stipulated natural attenuation for the contaminant of concern. This matter was discussed between us during an earlier onsite visit to Fort Monmouth. At the time you verbally recommended that we install additional monitoring wells and collect subsequent ground water samples to better support our natural attenuation approach. The DPW installed six monitoring wells (two-inch diameter wells) in August of 1998. The wells were placed down gradient of the landfill, adjacent to Mill Creek, spaced at 200 to 300 foot intervals. Following the well installations, four ground water sampling events were completed during three consecutive quarterly periods. Each sample was analyzed for TCL plus 30 parameters and TAL metals. Polychlorinated biphenyls (PCB) have been identified within two of the six monitoring wells (M2MW06 and M2MW09). The analytical results for the two wells can be viewed in Tables 1 and 2.

Table # 1

Monitoring Well M2MW-06

Sample Date	Purge Rate (Milliliters/Minute)	Contaminant of Concern	Result (ug/L)	NJDEP GW Quality Criteria
10/19/98	795	PCB	0.865	0.50
11/2/98	795	PCB	2.260	0.50
2/3/99	871	PCB	0.611	0.50
6/15/99	757	PCB	ND	0.50
7/20/99	871	PCB	0.581	0.50

Table # 2

Monitoring Well M2MW-09

Sample Date	Purge Rate (Milliliters/Minute)	Contaminant of Concern	Result (ug/L)	NJDEP GW Quality Criteria
10/19/98	681	PCB	4.55	0.50
11/2/98	681	PCB	1.73	0.50
2/3/99	871	PCB	1.431	0.50
6/15/99	871	PCB	ND	0.50
7/20/99	871	PCB	1.456	0.50

In an effort to determine the source of the PCB contamination, the DPW has collected soil samples within the vicinity of wells M2MW-06 and M2MW-09. PCBs have been identified within site soils. Furthermore, PCBs were identified within the soil column just above the water table. It is our belief that the PCB levels observed within the ground water at wells M2MW-06 and M2MW-09 are a function of PCB oils adhering to soil particles which are being drawn into the saturated section of the monitoring well during the course of well purging and sampling activities. We therefore conclude that the PCB contamination identified in earlier sampling rounds is not a true indication of their presence within site ground water.

In order to substantiate our position, the DPW proposes to collect two rounds of ground water samples from each well under a low flow purge and sampling procedure. The attached Field Sampling and Quality Assurance Plan is hereby submitted for your review and approval. Should you have any questions or require any additional information at this time, the undersigned can be contacted at the following telephone number: (732) 532-6223.

Sincerely,

Joseph M. Fallon

III PRELIMINARY SITE ACTIVITIES	2
IV SAMPLING PROCEDURE	2
V DECONTAMINATION	4
VI FIELD QUALITY CONTROL	4
VII FIELD LOGBOOK	4
VIII SAMPLE IDENTIFICATION	4
IX SAMPLE CUSTODY	5

I INTRODUCTION

ATC Associates has been retained by the Fort Monmouth Directorate of Public Works (DPW) to conduct a sampling event, using low flow purging and sampling, at landfill site M2. All project activities will be conducted in accordance with this Field Sampling and Quality Assurance Plan (FSQAP), and with the *New Jersey Department of Environmental Protection, Site Remediation Program, Technical Requirements for Site Remediation* N.J.A.C. 7.26E, (Technical Requirements).

The data generated during these activities will be used to evaluate the groundwater quality associated with two monitoring wells (site M-2) for the purpose of confirming the presence of PCBs and elevated metals concentrations.

The NJDEP will be notified prior to the commencement of on-site investigation activities.

This FSQAP, which was prepared following the Technical Requirements, and Ground Water Sampling Guidelines for Low Flow Pump Purging and Sampling procedure, will ensure that field sampling procedures, analytical methods selected, and chemical analytical data are of sufficient quality to meet the intended uses. The recommended procedure will, in most situations, provide for the collection of ground water samples with minimum turbidity. This procedure is designed to be used in conjunction with the analyses for the most common types of ground water contaminants (volatile and semi-volatile and semi-volatile organic compounds, pesticides, PCBs, and inorganic compounds).

The site investigation activities will include groundwater sampling in the following areas:

Landfill M2, monitoring wells MW-06 and MW-09;

II EQUIPMENT

Low flow-rate peristaltic pumps will be used. A peristaltic pump is a self-priming suction lift pump, utilized at the ground surface, which consists of a rotor with ball bearing rollers. The liquid being pumped moves totally within the sampling tube, and no part of the pump contacts the liquid, greatly simplifying decontamination procedures.

Silicone tubing will be used in the pumps. The tubing on either side of the pump will be Teflon® tubing. The Teflon® tubing used in purging and sampling each well will be dedicated to the individual well.

A water level measuring device with 0.01 floor accuracy, a graduated cylinder, an in-line purge criteria parameter monitoring instrument (for pH, specific conductance, temperature, and dissolved oxygen), a turbidity meter, and a stop watch will be used for flow measurements.

III PRELIMINARY SITE ACTIVITIES

1. Check well for damage or tampering, record pertinent observations.

2. Lay out sheet of polyethylene for monitoring and sampling equipment.

3. Measure VOCs (volatile organic compounds) at the rim of the unopened well with a PID or FID instrument and record the reading in the field logbook.

4. Remove well cap.

5. Measure VOCs within the well casing with a PID or FID instrument and record the reading in the field logbook.

6. Measure and record the depth to water (to 0.01 ft) in all wells to be sampled before any purging begins. Care will be taken to minimize disturbance to the water column and to any particulate attached to the sides or at the bottom of the well.

7. During previous sampling events, no DNAPL was detected within the two monitoring wells. Based upon this information, DNAPL measurements will be conducted following sample collection. This procedure will minimize disturbance to the water column prior to sampling activities.

IV SAMPLING PROCEDURE

The equipment specified in Section II of this Guideline will be used to purge and sample the monitoring wells. The sampling procedure is as follows:

1. The sampling tube will be lowered slowly into the well to a depth corresponding to the center of the saturated screen section of the well. The end of the tube will be kept above the bottom of the well to prevent mobilization of any sediment in the bottom of the well.

2. The water level will be measured again before starting the pump.

3. The well pumping will start at 200 to 400 milliliters per minute (ml/min). The pumping rate should cause little or no water level drawdown in the well (less than 0.2 ft. and water level should stabilize). The water level will be monitored every three to five minutes during pumping. Care will be taken not to cause pump suction to be broken, or entrainment of air in the tubing. All pumping rate adjustments and depths to water will be recorded. Pumping rates will, if needed, be reduced to the minimum capabilities of the pump to avoid pumping the well dry and/or to ensure stabilization of indicator parameters. If the recharge rate of the well is very low, purging will be interrupted so as not to cause the drawdown within the well to advance to the end of the tube. However, a steady flow rate will commence as soon as the volume in the well has recovered sufficiently to permit collection of samples.

4. During purging of the well, in-line water quality indicator parameters (pH, specific conductance, temperature, and dissolved oxygen) and turbidity will be monitored every three to five minutes. The well will be considered stabilized and ready for sample collection once all the field indicator parameter values remain within +/-10% for three consecutive readings, with the exception of +/-0.05 units for pH. If the parameters have stabilized, but the turbidity is not in the range of the 5-10 NTU goal, then the pump flow rate will be decreased to no more than 100 ml/min. If all the parameters have again stabilized, or if all parameters except turbidity have again stabilized, sampling of the groundwater will commence.

5. PCB and TAL metal samples will be collected and placed directly into pre-preserved sample containers. The tubing will be disconnected from the in-line monitoring instrument prior to collecting each sample. All sample containers will be filled by allowing the pump discharge to flow gently down the inside of the container with minimal turbulence.

6. As each sample is collected, the sample will be labeled. All samples requiring cooling will be placed into an ice cooler maintained between 3° C and 5° C for delivery to the laboratory.

7. After collection of the samples, the Teflon® tubing will be placed in polyethylene bags labeled with the monitoring well designation and stored for subsequent sampling events. If no future events are planned, the Teflon® tubing will be discarded. The silicone tubing used in the pumps will be discarded after each sample is collected.

8. Following sample collection, a depth to groundwater measurement for each well will be recorded.

9. The well will be secured.

V DECONTAMINATION

Since dedicated tubing will be used, and since groundwater to be sampled will not come into contact with any of the equipment common to all the wells purged, no decontamination of equipment is necessary.

VI FIELD QUALITY CONTROL

Quality control samples are required to verify that the sample collection and handling process has not affected the quality of the ground water samples. All field quality control samples will be prepared exactly as regular investigation samples with regard to sample volume, containers, and preservation. The following quality control samples will be collected for each batch of samples (a batch will not exceed 20 samples):

- Field duplicate.

VII FIELD LOGBOOK

A field logbook will be kept to document the following:

- Well identification;
- Well depth, and measurement technique;
- Static water level depth, date, time, and measurement technique;
- Field observations of sampling event;
- Weather conditions;
- QA/QC data for field instruments.

VIII SAMPLE IDENTIFICATION

1. Each container will be labeled by the sampler to avoid any possibility of sample misidentification.

2. At a minimum, each label will contain the following information:

- Site Name;
- Sample designation number (field number);
- Sample description (sample type);
- Date sampled;
- Time sampled;
- Sampler's name;
- pH adjustment: acid/base used, pH achieved (preservative);
- Analysis requested.

3. U.S. Army Fort Monmouth Environmental Testing Laboratory (NJDEP Certification ID#13461) will be utilized for sample analysis. Upon arrival at the laboratory, each sample will be assigned a unique laboratory identification number that will be used for analysis assignment, sample tracking, and data reporting while the samples are at the laboratory.

IX SAMPLE CUSTODY

Samples for chemical analysis, which collected on each sampling day, will be considered under custody if:

1. They are in possession.

2. They were in possession and were locked up or sealed in a tamper-proof manner.

3. They are placed in a designated secure area.

Empty, clean, preserved sample containers will be relinquished by the laboratory with a chain-of-custody record. The chain-of-custody record will be used for all samples collected. Any transfer of custody of containers or samples will be noted on the chain-of-custody record. Each sample collected for the project will be entered on the chain-of-custody record and the original chain-of-custody record will accompany the sample containers during transport to document their custody.

The laboratory will assume custody of the samples upon receipt and a designated sample custodian will be charged with sample receipt, completion of custody records, checking correctness of sample documentation, sample log-in, and sample distributions. All samples will be logged in a bound, volume-numbered custody logbook, or into the laboratory information management system.

The following information will be supplied to complete the chain-of-custody record:

a. Project name;

b. Signature of samplers;

c. Sampling station number, date and time of collection, grab or composite sample designation, and brief description of the type of sample; sampling location; and analysis parameters;

d. Signatures of individuals involved in sample transfer, i.e., relinquishing and accepting samples. Individuals receiving the samples shall sign, date, and note the time that they received the sample on the form;

e. In the lower right comment section, the type of carrier service will be indicated.

At the end of the sampling day (for each bottle shipment), all samples and blanks for chemical analysis will be packaged in sample coolers on "wet ice" for delivery to the analytical laboratory. All samples will be logged into the laboratory information management system (LIMS) immediately. The laboratory courier will assume custody of the samples on-site by signing the field Chain-of-Custody form. For the purposes of contractual analytical holding times, this signature will constitute the verified time of sample receipt (VTSR), however; actual time/date of sampling will be used for data evaluation purposes.

STANDARD OPERATING PROCEDURE

SOP No.: SAM-0205
Revision No.: 1
Date Revised: 8/9/99

CATEGORY: Sample Handling
TITLE: Monitor Well Sampling for IRP Sites at Fort Monmouth

1 PURPOSE:

To document current procedures for monitoring well sampling.

2 RESPONSIBILITY:

Designated field samplers who have been properly trained and instructed in NJDEP field sampling procedures and protocol.

3 REFERENCES:

3.1 Field Sampling Procedures Manual, May 1992 (most current). New Jersey Department of Environmental Protection and Energy.

3.2 Occupational Safety and Health Guidance Manual for Hazardous Waste Site Activities developed by NIOSH, OSHA, USCG, EPA. Oct. 1985

3.3 NJDEP Field Analysis Manual, July 1994.

3.4 On the World Wide Web: www.state.nj.us/dep or www.state.nj.us/dep/srp.

3.5 Lab SOP: SAM-0200, SAM-0202, OQC-0302

4 SUMMARY:

The procedures, materials, and equipment describe the recommended methods for sampling monitoring wells. Necessary equipment, calibrations, calculations and appropriate QA/QC procedures are also included. These procedures are to be followed by all personnel involved with the sampling and purging of wells at Fort Monmouth. Persons following this SOP are recommended to also refer to the NJDEP Field Sampling Procedures Manual.

Prepared By L. Wright Date 8-11-99

Approved By Jackie Hamer Date 8/11/99
QA Manager / Laboratory Director

5 EQUIPMENT AND MATERIALS:

5.1 Equipment

5.1.1 Dissolved oxygen meter
5.1.2 HNU photo ionizer
5.1.3 Conductivity/pH/temp meter
5.1.4 Peristaltic well pumps
5.1.5 Pump heads and power cables
5.1.6 Water level meter
5.1.7 Oil/water interface probe
5.1.8 Submersible well pumps
5.1.9 Various batteries
5.1.10 Buckets
5.1.11 Miscellaneous tools, i.e. screwdriver, well wrench, etc.

5.2 Materials:

5.2.1 Thick wall silicone tubing ¼ inch diameter,
5.2.2 Polyethylene (food grade) tubing ¼ inch diameter,
5.2.3 12 inch single sample 1 check stop teflon disposable bailers,
5.2.4 Mason string.

6 STANDARDS/REAGENTS:

6.1 Buffer solutions, calibration gases, decontamination materials, and acids for preservation.

6.1.1 Buffer solutions:

6.1.1.1 7.00 standard buffer solution
6.1.1.2 10.00 standard buffer solution
6.1.1.3 4.00 standard buffer solution
6.1.1.4 Distilled and deionized water
6.1.1.5 Alconox
6.1.1.6 10 % nitric acid rinse (trace metal or higher grade HNO3 diluted with distilled/deionized (ATSM Type II) H2O)
6.1.1.7 Acetone (pesticide grade)
6.1.1.8 Pure nitrogen 100 ppm Isobutylene cal gas.

6.1.2 Acids/materials used in preserving samples:

6.1.2.1 Nitric acid 69, 0-70.0%
6.1.2.2 Sulfuric acid 50% (w/w) solution
6.1.2.3 Hydrochloric acid (trace metal grade)
6.1.2.4 Ice for keeping samples at <4 degrees celcius.

Refer to NJDEP Field Sampling Procedure Manual Table 2-1 Aqueous Sampling Equipment Decontamination (Lab and Field).

7 CALIBRATION:

All instruments used for field readings are calibrated before each day of use. The use of pH meters must start out with a calibration using buffer solution standards to check or calibrate accuracy. HNU's are calibrated with a known calibration gas. Dissolved oxygen meters are checked against a winkler method test weekly. All calibrations for a given day's use are recorded in the log provided for each instrument. Refer to equipment directions for calibration instruction. Likewise, specific conductivity meters are checked against standards regularly. Cooler thermometers are calibrated against an NIST traceable thermometer annually.

8 PROCEDURE:

The following articles document the procedures for sampling monitor wells. They are to be used as a guide, by trained personnel, in conjunction with the NJDEP Field Sampling Procedures Manual.

8.1.1 Preparation: It should be noted that before going out into the field, certain preparations must be made. This includes the selection of PPE, safety plans, proper bottle acquisition for analytes being tested, site entry, map information, and equipment.

8.1.2 Selection of PPE: For adequate protection and prevention of contaminant exposure to workers at hazardous waste sites in all phases of work, PPE is properly used and supplied. Determination of PPE will be outlined in a Health and Safety Plan, and also by preliminary site investigations. Refer to NJDEP Field Sampling Procedures Manual, and the Occupational Safety and Health Guidance Manual for Hazardous Waste Site Activities.

8.1.3 Health and Safety Plans: These plans are developed to encompass all the aspects of site operations. Plans are available to personnel associated with site sampling and a copy is kept on file at the site (in this case, the laboratory). At a minimum, the plan includes all portions of Site Remediation Program's (SRP) Site Safety and Health Standard Operating Procedures deemed appropriate for site, detailed site description, emergency phone numbers, a map and directions to nearest hospital identified on the map, and all PPE needed.

8.1.4 Proper bottle selection: Please refer to QA/QC section 10.1.

8.1.5 Equipment: Please refer to Equipment section 5.

8.1.6 Before purge activities: Certain instruments and meters are calibrated before use. Also, certain measurements and calculations are obtained before any purge activities take place. The following is a list of information/data/steps required prior to the commencement of purge activities. Pertinent information is recorded in log books or on well sheets.

8.1.7 Date, time and weather conditions: Date and time are needed for holding time purposes and general record keeping. Weather conditions may affect ambient conditions at a particular site, therefore said information is recorded. Tidal influences may also be included here, if wells are in a tidal area.

8.1.8 Well number and permit number: These are prominently displayed on the outside of each well in accordance with NJDEP regulations for well construction.

8.1.9 Meter and instrument calibrations: Meters utilized in the course of site sampling activities are calibrated at this time, and the findings recorded in the appropriate logbook. Refer to section 7 for instrument/meter calibration directions.

8.1.10 PID or FID, HNU reading: This is taken from the well inner casing immediately after the cap is removed, findings are recorded.

8.1.11 Free product check: Using ORS meter for interfaces, the presence or absence of free product is determined. Thickness is measured and recorded.

8.1.11.1 Light Non-Aqueous Phase Liquids (LNAPLs) and Dense Non-Aqueous Phase Liquids (DNAPLs): Measurement of thickness for DNAPLs and LNAPLs are performed prior to well purging. An interface probe is used (ORS meter) for this task. If present, LNAPLs are sampled and analyzed for chemical and physical parameters. Sampling is conducted by using a bottom filling bailer which is lowered into the LNAPL layer. DNAPLs are sampled using a dual check valve bailer. If present, DNAPLs are also tested for chemical and physical properties.

8.1.12 Dissolved oxygen, pH, temperature, and specific conductivity: Readings are obtained and recorded on well sheets.

8.1.13 Total depth of well and depth to water: These readings are taken using a depth meter. Total depth of well, depth to water, and depth to screen are measured from the top of the inner casing or surveyors mark. All data is recorded on well sheet.

8.1.14 Calculations: Calculations are made as stated in section 9.

8.2 Purging: When pre-purge activities are complete, the purging of a well can begin. This includes pre-entry to the well and pump setup.

8.2.1 Pre-entry to well: Before tubing (refer to materials section) is inserted into a well, it is wiped down and rinsed with DI water. The tubing is then inserted into the well to a maximum depth of six feet below the water table. During purge activities, the depth of the tubing may be adjusted to prevent the static water level from dropping below the end of the tubing.

8.2.2 Pump setup: Once the battery powered peristaltic pump is set up, purging can begin. Evacuation rates never exceed that of well development, and total volume purged never exceeds 5 times the amount of standing water. Purge water management practices are described in section 10.1.8.

8.3 After Purge: When purging is complete, the pump is removed and tubing is disposed of properly. Data referenced in section 8.3.2 is then taken and recorded.

8.3.1 Pump removal: Tubing is removed from the bottom end while the pump is still running. Tubing is then disposed of. The pump is shut down and decontaminated for its next application.

8.3.2 The following data is recorded on the well sheet: Start and end time of purge, purge method, purge rate, total volume purged, dissolved oxygen, pH, temperature, and specific conductivity readings.

8.4 Field Blank Sample: At this time the field blank sample is collected. A new bailer is opened from its sealed package and field blank water is run over the bailer or sample equipment and collected into the proper sample containers.

8.5 Ground water sampling: Following well evacuation procedures, ground water sampling can begin. In most cases, sampling takes place immediately following purge activities. However, due to certain field conditions, well sampling may be postponed for a period not to exceed 2 hours following completion of purge activities. When multiple wells are being sampled, the least contaminated well is sampled first. Subsequent wells are sampled in order of ascending contamination. Sampling is conducted by using a bottom filling teflon bailer, dedicated to each particular monitoring well. The bailer is lowered slowly into water column until submerged, and then slowly retrieved. The sample is then carefully transferred to the appropriate sample containers. Ground water collected in the first bailing sequence is always used for sampling purposes, it is never discarded.

8.6 Sample order: Samples are collected in the following order:

- 8.6.1 volatile organics (VOA)
- 8.6.2 purgeable organic carbons (POC)
- 8.6.3 purgeable organic halogens (POX)
- 8.6.4 total organic halogens (TOX)
- 8.6.5 total organic carbon (TOC)
- 8.6.6 base neutrals/acid extractables
- 8.6.7 TPHC/oil and grease
- 8.6.8 PCB's/pesticides
- 8.6.9 total metals
- 8.6.10 dissolved metals
- 8.6.11 phenols, cyanide
- 8.6.12 sulfate and chloride
- 8.6.13 turbidity
- 8.6.14 nitrate and ammonia,
- 8.6.15 preserved inorganics
- 8.6.16 radionuclides
- 8.6.17 non-preserved inorganics
- 8.6.18 bacteria

8.7 Dupes and matrix spikes/matrix spike duplicates: These samples are taken in same order at same time. Refer to section 10.2.1.2.

8.8 After sampling: The following data is recorded on well sheets: Start and end time of sampling, dissolved oxygen, pH, temperature, specific conductivity, and sampling method.

9 CALCULATIONS:

Four calculations are made while in the field. The calculations are as follows: linear feet of water (height of water), the volume to be purged, the volume purged not to be exceeded, and purge rate.

9.1 Linear feet of water: This is calculated by knowing the total depth of a well and subtracting the depth to water as measured by a depth meter. These two numbers are measured to within .01 feet. Through this calculation, the linear feet of water is determined.

Equation: (Total well depth – Depth to water = linear feet of water)

9.2 Volume to be purged and volume not to be exceeded: The second calculation is to determine the minimum volume to be purged from a well before sampling. Utilizing the linear feet of water and then multiplying it by the volume per foot for the proper diameter casing (see Figure 1 below) equals the amount of water in casing. Multiplying the amount of water within a casing by 3 equals the minimum volume to be purged. It should be noted that the amount purged should not exceed 5x the amount of standing water in a well.

Equation:
linear feet of water x volume per ft for well diameter = amount of water in casing)
then,
(amount of water in casing x 3 = minimum volume to be purged)

Equation:
(amount of water in casing x 5 = total volume not to be exceeded)

Figure 1: Capacity of Common Casing Diameters
(Pp. 170 in NJDEP FSPM)

Casing Diameter (ft.)	Gallons/linear foot
2 inch (0.1667)	0.1632
4 inch (0.3333)	0.6528
6 inch (0.5000)	1.4688
8 inch (0.6667)	2.6112
10 inch (0.8333)	4.0800
12 inch (1.0000)	5.8752

9.3 Purge rate: The purge rate is determined by calculating the length of time it takes for a pump to fill a 1 gallon bucket with water. The time is then multiplied by the minimum volume to be purged. The gallons being purged is then divided by this number (which also happens to be the length of time the purge will take in minutes) which equals the gallons per minute or purge rate.

Equation:
(time x minimum volume to be purged = length of purge in minutes)
then,
(minimum volume to be purged / length of purge in minutes = gallons per minute or the purge rate)

10 QUALITY CONTROL:

The following QA/QC requirements are established in order to maintain sample integrity. The prime objective is to prevent sample contamination from other sources and ensure potential contaminant concentrations remain stable from sample collection to complete analysis. Refer to the NJDEP Field Sampling Procedures Manual Appendix 2-1 Analytical Methodology Reference Charts, Pp. 24-74. Also refer to SAM-0200 Sample Containers, Preservation and Holding Times.

10.1 Sample Containers: Before sample collection can begin consideration must be given as to what type container will be used to transport and store samples. The lab provides containers based upon requested methodologies. Selection is based on the matrix, potential contaminants, analytical methods, and the laboratory's internal QA/QC requirements. They are selected upon review of the following:

10.1.1 Reactivity of container material with sample. Glass is recommended for hazardous material samples since it is chemically inert to most substances. Plastics may be used when analytes of interest or sample characteristics dictate use instead of glass.

10.1.2 Volume of the container. The volume of sample needed is dictated by the analytical method and the sample matrix. The laboratory supplies bottles that allow for sufficient volumes of sample matrix to be collected.

10.1.3 Color of container. Whenever possible, amber glass is used to prevent photodegradation. If not available, samples are protected from light. One exception is the use of 40 ml clear glass vials which are used for VOA/aqueous analysis.

10.1.4 Container closures. All containers utilized have a leak-proof seal and are constructed out of inert material with respect to sampled materials. The closure may also be separated by a closure liner that is inert to sample material.

10.1.5 Decontamination of containers and chain of custody. Sample containers are laboratory cleaned or purchased as lab cleaned. Bottles being shipped are accompanied by a chain of custody in a cooler with a custody seal. Custody always accompanies containers to the field, during collection, back to lab, and during analysis. This helps to assure no tampering or contamination from outside sources occurs.

10.1.6 Storage and transport. Care is taken to avoid contamination. Clean transport and storage environments are observed. Sample or bottle storage is never near solvents, gasoline, or other equipment that is a potential source of contamination. Samples and chain of custody are secured in coolers or transport, with said chain of custody in with bottles or in the possession of authorized personnel. Also, a temperature blank is included in each cooler to measure temperature of samples on ice (ideally a constant 4 degrees Celsius).

10.1.7 Tubing decontamination: ASTM drinking water grade polyethylene tubing is used and discarded after each use. Care is taken to prevent the pump and tubing from coming into contact with the ground surface. Prior to well purging, all tubing is rinsed/wiped with distilled and deionized water to remove any possible residual materials which may be present.

10.1.8 Disposal of development, purge, pump test, and decon waters: To determine whether waste waters are contaminated, field instrument readings and previous analytical data is used to characterize it. Water not considered contaminated is re-applied directly to ground surface and permitted to percolate back to the water table. Care is taken to avoid nuisance situations where a discharge may cause undue concern. When water is considered contaminated, the water generated is reapplied only if the following conditions are met: ground water is not permitted to migrate offsite, no potential exists for contaminating a previously uncontaminated aquifer, discharge will not cause an increase to ground surface soil contamination. If these conditions are met, the water is re-applied to the ground surface. If these conditions aren't met, than water

is collected, containerized and secured in a single locale. Subsequently, the water is properly characterized and processed for offsite disposal.

10.2 QA/QC samples: These samples are intended to provide control over the collection of environmental measurements and subsequent validation, review, and interpretation of analytical data. Trip blanks are used exclusively for volatile organic analysis, (aqueous sampling only) and their purpose is to measure possible cross contamination of samples during shipment to and from a site. Trip blanks are never opened and travel to a site with the empty sample bottles and back from a site with the collected samples. Contaminated trip blanks may indicate bottle cleaning or blank water of questionable quality. Trip blanks are collected at the rate of one per day. Likewise, the purpose of a field blank is to place a mechanism of control on sample equipment handling, preparation, storage and shipment. Field blanks travel and are stored with the sample bottles. Field blanks are collected in the following manner. Two identical sets of bottles are prepared. One set is filled with laboratory demonstrated analyte free water (same water used for trip and method blanks). All of the filled bottles are shipped with the other empty sample containers. At the field location, in an area where contamination is suspected, the water is passed from the full set of like-bottles through the dedicated or field decontaminated sampling device and into the empty set of like-bottles. Field blanks are preserved identically to samples receiving the same analyses. Field blanks are collected and analyzed for all of the same parameters as the samples collected that day.

10.2.1 Additional QA/QC samples:

10.2.1.1 Duplicate samples: Collection of a dupe provides for evaluation of laboratory performance by comparing the analytical data of two samples from the same location. They are included 1 for every 20 samples (5% or 1 a day/site) and submitted as blind samples. They are obtained by alternately filling sample bottles from the same source/device for each parameter. VOA samples are same bailer and first set filled.

10.2.1.2 Matrix spike/Matrix spike duplicate analyses or MS/MSDS sample: The laboratory is supplied with triple volume in order to perform matrix spike and matrix spike dupes. This does not include trips or field blanks. Additional sample volume for MS/MSDS is taken within every set of 20 field samples.

10.3 Sample preservation: Sample bottles are preserved by lab staff based upon analytical requirements. Please refer to SAM-0200 Sample Containers, Preservation, and Holding Times SOP and also NJDEP Field Sampling Procedures Manual Appendix 2-1 Analytical Methodology reference Charts, Pp. 24-74.

APPENDIX D

AQUIFER TEST RESULTS
M-2 LANDFILL

Slug and Pump Test Evaluation
Appendix D.1 – Aquifer Test Graphs

Aquifer Test Results – M2 Landfill

Slug Test Results

Rising head slug tests were conducted on five wells on the M2 landfill. Data was recorded using an InSitu SE10000 (Hermit) environmental data logger. Results were analyzed using the AquiferWin32 software. All results presented below were based on the Bouwer & Rice method of slug test interpretation. All lines were placed manually to achieve a better fit with the data than was achieved by computer optimization alone. Recovery graphs for the five wells are presented in Appendix D.1. Results were also interpreted with the Cooper, Bredehoft, and Papadopolous method, however, this method failed to converge to a unique solution.

Table D.1 summarizes the results of the slug test analyses. Results ranged from $5.1x10^{-6}$ feet (ft)/day at well MW20 to $1.2x10^{-6}$ ft/day at MW12, both of which are 53-foot deep wells. The three shallow wells, MW13, MW18, and MW23, had an average hydraulic conductivity of $2.0x10^{-6}$ ft/day. In contrast, deep wells MW12 and MW20 had an average hydraulic conductivity of $3.2x10^{-6}$ ft/day.

These results appear to suggest that the hydraulic conductivity may increase slightly with depth. However, a more correct interpretation may be that the shallow hydraulic conductivity is a relatively consistent $2.0x10^{-6}$ ft/day while the deeper hydraulic conductivity varies considerably from $5.1x10^{-6}$ ft/day to $1.2x10^{-6}$ ft/day. Care should be taken in utilizing these results since they are based on only three wells in the shallow zone (about 20 ft deep or less) and two wells in the deeper zone (over 50 ft).

Pump Test Results

A five-hour pump test was conducted at the M2 landfill using well MW19 (53 ft deep) as the pumping well and well MW24 (22 ft deep) as an observation well. A discharge rate of three gallons per minute (gpm) was maintained for the first 280 minutes (four hours and 40 minutes). The discharge rate was then increased to six gpm for an additional five minutes. Finally, the discharge rate was increased to 8 gpm for an additional five minutes. Data on the pumping well was recorded using an InSitu SE 1000 (Hermit) data logger as well as periodic hand measurements. Drawdown in shallow well MW 24 was recorded by periodic hand measurements.

Results were analyzed using the AquiferWin32 software. Curves were fit using a combination of computer optimization with manual adjustment. Several interpretation methods were used to explore different aspects of the test data. These included the effective aquifer type (i.e., confined vs. unconfined), partial penetration, storage, and changes in pumping rate. Results of the interpretation are summarized in Table D.2. Graphs for the analyses are included in Appendix D.1.

Results for well MW19 yielded a transmissivity of approximately 135 gallons per day per foot of drawdown. These data were analyzed with four different methods. The Cooper & Jacob method for unconfined aquifers, the Hantush methods for leaky aquifers with storage, the Neuman

method for unconfined aquifers with partially penetrating wells, and the Eden & Hazel method for step tests. With one exception, all methods yielded transmissivities of approximately 135 gpd/ft. The Neuman method for unconfined aquifers with partially penetrating wells yielded a transmissivity of approximately 120 gpd/ft. The Eden & Hazel method was also used to analyze the data from well MW19 as it was pumped at six gpm. This analysis yielded a transmissivity of 72 gpd/ft. However, the data record was so short these results may not be reliable. The data record for the pumpage at 8gpm was too short to analyze. Care should be taken in utilizing these results because drawdown measurements made on a pumping well are often subject to errors because of well losses and storage effects.

Results for the shallow observation well MW 24 were analyzed using the two Theis methods for confined aquifers and for unconfined aquifers with partial penetration, as well as the Hantush method for confined aquifers with partial penetration. Results for the confined aquifer methods yielded transmissivities of approximately 315 gpd/ft. Results for the unconfined Theis method yielded a transmissivity of 381 gpd/ft. Because the shallow well is almost certainly under unconfined conditions, the higher transmissivity is probably more representative of the geologic materials at the site. Care should be taken in utilizing these results because the 15-foot screened portion of the observation well is 10 ft shallower than the 20-foot screened portion of the pumping well.

Estimates of the storage coefficient yielded results that were generally less than 1×10^{-6} with one exception. The Hantush methods for leaky aquifers with storage yielded a storage coefficient of 0.01. There are two ways to interpret these results. First, it could be assumed that the Hantush method of data analysis is the most appropriate method. In this case, the aquifer at the M2 landfill is an unconfined, leaky aquifer with storage having a transmissivity of 135 gpd/ft and a storage coefficient of .01. Second, it could be assumed that all of the data interpretation methods had some degree of appropriateness. In this case, the aquifer at the M2 landfill would have a transmissivity of approximately 380 gpd/ft in the shallow (less than 20 ft deep) zone which decreases to about 135 gpd/ft with depth (about 50 ft). The very low storage coefficients would then suggest that the aquifer has little effective porosity.

Comparison of Slug Test and Pump Test Results

It is not possible to compare directly the slug test and pump test results without knowing the saturated thickness of the aquifer at the M2 landfill. However, based on this data it appears that the slug tests have greatly underestimated the aquifer's hydraulic conductivity relative to the pump test. Assuming the pump test analyses are correct, the slug test results are probably too low by several orders of magnitude.

Table D.1 Summary of Slug Test Results

Well		MW12	MW13	MW18	MW20	MW23	*Averages*

EXECUTIVE SUMMARY

A search of available records was conducted by Environmental Data Resources, Inc. (EDR). The EDR Risk Management Plan Map Report provides information which may be used to comply with the Clean Air Act Risk Management Program 112-R. *"The rule requires that you estimate in the RMP residential populations within the circle defined by the endpoint for your worst-case and alternative release scenarios (i.e., the center of the circle is the point of release and the radius is the distance to the endpoint). In addition, you must report in the RMP whether certain types of public receptors and environmental receptors are within the circles."*

The address of the subject property, for which the search was intended, is:

The Geographic Names Information System (GNIS), developed by the USGS in cooperation with the U.S. Board on Geographic Names (BGN), contains information about almost 2 million physical and cultural geographic features in the United States. The GNIS is our Nation's official repository of domestic geographic names information.

PRV_SCH: Private Schools
EDR indicates the location of buildings and facilities - private schools - where individuals who are public receptors are likely to be located.

DAYCARE: Daycare Centers
EDR indicates the location of buildings and facilities - daycare centers - where individuals who are public receptors are likely to be located.

MEDCEN: Medical Centers
EDR indicates the location of buildings and facilities - medical centers - where individuals who are public receptors are likely to be located.

NURSING: Nursing Homes
EDR indicates the location of buildings and facilities - nursing homes - where individuals who are public receptors are likely to be located.

ARENA: Arenas
EDR indicates the location of buildings and facilities - arenas - where individuals who are public receptors are likely to be located.

PRISON: Prisons
EDR indicates the location of buildings and facilities - prisons - where individuals who are public receptors are likely to be located.

BOP: Bureau of Prisons Facilities
Source: Federal Bureau of Prisons
List of facilities operated by the Federal Bureau of Prisons.

Fort Monmouth, New Jersey

	WELL OWNER	WELL ADDRESS	WELL DESIGNATION	WELL USE CODE	WELL DEPTH (ft)	WELL CAPACITY	PERMIT NUMBER	PERMIT DATE	NJGRID	LATITUDE	LONGITUDE	DRILLER	WELLDATE	COMP. DATE	FIN. DEPTH	WELL CONTACT (if identified)

Source: State of New Jersey Department of Environmental Protection - Well Permitting and Regulations Section of the Bureau of Water Allocation, Trenton, NJ.
Search date: 18 January 2001.
Well search was performed for a 1-mile radius surrounding the center point of the M-2 Landfill, U.S. Army Garrison Fort Monmouth, Fort Monmouth, New Jersey.

Well Use Codes

A - Unknown/Well Record Use Only
B - Boring
C - Commercial
D - Domestic (Potable)
E - Recovery/Decontamination Pollution Control/Leachate with Pump Capacity
F - Fire
G - Irrigation
H - Heat Pump/Geothermal (Return Well)
I - Industrial
J - Injection
K - Inclinometer
L - Livestock
M - Monitoring Well (Observation)
N - Public Non Community
O - Oil/Gas Exploration
P - Public Supply
Q - Recharge
R - Replacement (Replacement Codes: 1 - Domestic; 2 - Public Community, 5 - Irrigation)
S - Closed Loop
T - Test
U - Non Public (Supply)
V - Gas Vent
W - Dewatering
X - Agricultural/Horticultural/IrrigationWells
Y - Cathodic Protection
Z - Piezometer

METHODOLOGY SUMMARY

Methodology Summary

EPA SW-846 Method 608
Polychlorinated Biphenyls (PCBs) by Gas Chromatography

Aqueous samples are extracted in a separatory funnel with Methylene Chloride and solid samples by Sox-therm with a 50:50 mixture of Acetone and Hexane. The extract is then dried and exchanged to hexane to a final volume of 10 ml. The extract is injected into a gas chromatograph onto two distinct capillary columns and measured by a micro-electron capture detector.

EPA SW-846 Method 8082
Gas Chromatographic Determination of PCB's in Soil

Surrogates are added to a 10-gram soil sample, which has been dried with sodium sulfate. The sample is then extracted using a soxtherm extractor. The extract is concentrated to 10 ml. Internal standards are added and the extract is injected into a GC/ECD system. PCB's are identified and quantitated. The final concentration is calculated using soil weight, percent moisture and concentration.

CASE NARRATIVE

CASE NARRATIVE

Site: M-2 Landfill / PCB Investigation

Lab ID: 4281, 4285, 4290, 4294, 4299, 4307, 4313, 4316, 4320, 4890, 4903, 4963, 4965, 5119, 5148

Soil samples taken at MW17 and MW20 reflect the new names for these wells. The new names are M2MW06 and M2MW09 respectively.

Soil samples taken on 2/24/99 were cancelled. These are samples from boring 17 and they were resampled on 3/1/99 as Lab ID 4307.

Sample ID	Cancelled Lab ID	New Lab ID
17 0-6"	4299.03	4307.01
17 12-18"	4299.04	4307.02
17 24-30"	4299.05	4307.03
17 36-42"	4299.06	4307.04
17 48-54"	4299.07	4307.05
17 60-66"	4299.08	4307.06

Aqueous samples were not taken at locations 28, 29 and 30 due to limited vehicle access.

CASE NARRATIVE

Site: M-2 Landfill
PCB Delineation

Lab ID: 4963, 4965

The field duplicates that were sampled on 11/24/99 were performed on sample associated with 21-B.

METHOD SUMMARY

Method Summary

EPA Method 624
Gas Chromatographic Determination of Volatiles in Water

A 5-ml volume of sample is added to 5-ml aliquot of water. Surrogates and internal standards are added and the sample is placed on a purge and trap concentrator. The sample is purged and desorbed into a GC/MS system. Volatiles are then identified and quantitated.

EPA SW-846 Method 8260
Gas Chromatographic Determination of Volatiles in Soil

A 5-gram volume of soil sample is added to a 5-ml aliquot of water. Surrogates and internal standards are added and the sample is placed on a purge and trap concentrator. The sample as purged and desorbed into a GC/MS system. Volatiles are identified and quantitated. The final concentration is calculated using soil weight, percent moisture and concentration.

CASE NARRATIVE

CASE NARRATIVE

Site: M2 Benzene Investigation

The last samples taken on 3/18/99 were designated as 59 6' and 59 6.5'-9.5' (Lab ID #s 4358.09 and 4358.10) and the first samples taken on 3/23/99 were designated as 59 6' and 59 6.5'-9.5' (Lab ID #s 4368.03 and 4368.04). The letter "A" was added to the ID of the samples taken on 3/23/99 to differentiate between the two sets of samples.

SOIL CLEANUP CRITERIA

Soil Cleanup Criteria

Compound	mg/Kg
Acrolein	NLE
Acrylonitrile	1
tert-Butyl alcohol	NLE
Methyl-tert-Butyl ether	NLE
Di-isopropyl ether	NLE
Dichlorodifluoromethane	NLE
Chloromethane	520
Vinyl Chloride	2
Bromomethane	79
Chloroethane	NLE
Trichlorofluoromethane	NLE
1,1-Dichloroethene	8
Acetone	1000
Carbon Disulfide	NLE
Methylene Chloride	49
trans-1,2-Dichloroethene	1000
1,1-Dichloroethane	570
Vinyl Acetate	NLE
2-Butanone	1000
cis-1,2-Dichloroethene	79
Chloroform	19
1,1,1-Trichloroethane	210
Carbon Tetrachloride	2
Benzene	3
1,2-Dichloroethane	6
Trichloroethene	23
1,2-Dichloropropane	10
Bromodichloromethane	11
2-Chloroethyl vinyl ether	NLE
cis-1,3-Dichloropropene	4
4-Methyl-2-Pentanone	1000
Toluene	1000
trans-1,3-Dichloropropene	4
1,1,2-Trichloroethane	22
Tetrachloroethene	4
2-Hexanone	NLE
Dibromochloromethane	110
Chlorobenzene	37
Ethylbenzene	1000
Total Xylenes	410
Styrene	23
Bromoform	86
1,1,2,2-Tetrachloroethane	34
Anthracene	10000
Di-n-butylphthalate	5700
Fluoranthene	2300
Benzidine	NLE
Pyrene	1700
Butylbenzylphthalate	1100
Benzo(a)anthracene	0.9
3,3'-Dichlorobenzidine	2
bis(2-Ethylhexyl)phthalate	49
Di-n-octylphthalate	1100
Benzo(b)fluoranthene	0.9
Benzo(k)fluoranthene	0.9
Benzo(a)pyrene	0.66
Indeno(1,2,3-cd)pyrene	0.9

Compound	mg/Kg
Pyridine	NLE
N-nitroso-dimethylamine	NLE
Aniline	NLE
Phenol	10000
bis(2-Chloroethyl)ether	0.66
2-Chlorophenol	280
1,3-Dichlorobenzene	5100
1,4-Dichlorobenzene	570
Benzyl alcohol	10000
1,2-Dichlorobenzene	5100
2-Methylphenol	2800
bis(2-chloroisopropyl)ether	2300
4-Methylphenol	2800
n-Nitroso-di-n-propylamine	0.66
Hexachloroethane	6
Nitrobenzene	28
Isophorone	1100
2-Nitrophenol	NLE
2,4-Dimethylphenol	1100
bis(2-Chloroethoxy) methane	NLE
2,4-Dichlorophenol	170
Benzoic Acid	NLE
1,2,4-Trichlorobenzene	68
Naphthalene	230
4-Chloroaniline	230
Hexachlorobutadiene	1
2,4,6-Trichlorophenol	62
2,4,5-Trichlorophenol	5600
2-Chloronaphthalene	NLE
4-Chloro-3-methylphenol	10000
2-Methylnaphthalene	NLE
Hexachlorocyclopentadiene	400
2-Nitroaniline	NLE
Dimethylphthalate	NLE
Acenaphthylene	NLE
2,6-Dinitrotoluene	NLE
3-Nitroaniline	NLE
Acenaphthene	3400
2,4-Dinitrophenol	110
4-Nitrophenol	NLE
Dibenzofuran	NLE
2,4-Dinitrotoluene	1
Diethylphthalate	10000
Fluorene	2300
4-Chlorophenyl-phenylether	NLE
4-Nitroaniline	NLE
4,6-Dinitro-2-methylphenol	NLE
n-Nitrosodiphenylamine	140
4-Bromophenyl-phenylether	NLE
Hexachlorobenzene	0.66
Pentachlorophenol	6
Phenanthrene	NLE
Dibenz(a,h)anthracene	0.66
Benzo(g,h,i)perylene	NLE
Azobenzene	NLE
Chrysene	9

NLE- No Limits Established

QUALIFIERS

US ARMY FT. MONMOUTH ENVIRONMENTAL LABORATORY
NJDEP CERTIFICATION # 13461

Definition of Qualifiers

MDL : Method Detection Limit
J : Compound Identified Below Detection Limit
B : Compound is in Both Sample and Blank
D : Results are from a Dilution of the Sample
U : Compound Searched for but not Detected
E : Compound Exceeds Calibration Limit
